COAL AGE

With Which is Consolidated
The Colliery Engineer

INDEX TO VOLUME XXV

January 1 to June 30, 1924

NOTE—The articles and references in this index have been classified under leading subjects or topics, as far as practicable, and should be sought under such heads, which together with all unclassified matter are arranged alphabetically. Illustrated articles or cuts standing by themselves are indicated by an asterisk (*). All editorials appear under that subject, each having its exact title. Elsewhere the subject matter of an editorial will be found classified and marked (e). Many titles of articles are abbreviated, the aim being to give prominence to important words.

Following is a list of the pages included in each issue of the volume, together with date and number of the issue, for convenience of reference:

	No.	Pp.
Jan.	3	1-32
"	10	33-64
"	17	65-124
"	24	125-180
"	31	181-194
Feb.	7	195-230
"	14	231-266
"	21	267-302
"	28	303-340
March	6	341-376
"	13	377-412
"	20	413-448
"	27	449-482
April	3	483-518
"	10	519-554
"	17	555-590
"	24	591-624
May	1	625-660
"	8	661-712
"	15	713-750
"	22	751-794
"	29	795-828
June	5	829-864
"	12	865-898
"	19	899-932
"	26	933-968

—Motor for driving fan at variable speed.	
—Best type; Chadbourne.	*722
—Single and 3-phase motors, Newly developed.	*749
—Polyphase induction motor, Cast rotor of "Klydonograph" records abnormal voltage surges.	*750
—Relay indicates current flowing in line.	*816
—Copper-plated carbon brushes not necessary.	*864
—Temperature relays heats in same ratio as motor.	888
—Motor generator set, Automatically operated.	*898
—Rotary converter outfit.	*914
—Elec. mine lamps reduce fire hazard.	*914
—Phasing out a converter.	*921
—Feeder wire hanger for mine service.	*922
—Switch timed by synchronous motor.	*931
—Protected motor bearings, New types.	*946
—Keeps controller fingers and segments from burning.	*957
—Truck-mounted electric welding outfit.	*968
—Arc-welding outfit.	*968
Equipment, Steam	
—High-speed flexible coupling for turbine drives.	*230
—Steam turbine-generator lighting unit.	*376
—Steam-turbine plant, Switchboard for.	*631
—Air-heating unit, Motor-driven.	*864
—Flow meter with new integrating unit.	932
—Recording meters, Improved steam and air-flow.	*968

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 25

NEW YORK, JANUARY 3, 1924

Number 1

Sane Thinking on Transportation

CONSIDER for a moment the significance of the fact that the railroads have many friends. But a few years ago the most maligned industry, today befriended by all save La Follette and his radical following. What has brought about the change and why do we find the United States Chamber of Commerce coming to the rescue of the railroads at this critical juncture? Because the business men of this country have finally learned that it is fatal to make an important industry the plaything of politics. There was a time when the public was exploited by railroad financiers. That day is past and the carriers are paying for their past follies with surrender of their freedom to regulation.

But even regulated, they have rights and the shippers of the country have rights, of which there should be no surrender to politics. Hence the National Chamber is making the people think of transportation sanely. It has had a careful study made of the whole subject and will have a huge conference on transportation in Washington next week—not to solve the questions but to make people see the problems in other than the refulgent light of Congress' halls..

Why Not Telephone?

PERHAPS there is a reason why we do not have active "Coal Exchanges" in this country, such as are described by Paul Wooton in his article elsewhere in this issue. There are coal exchanges in a number of our cities, as Cincinnati, but they are not active buying and selling organizations, but rather more often social. The nearest approach to a coal exchange as found in England is that conducted under the amiable direction of Herman M. Griggs at Cleveland—the Lake Erie Ore & Coal Exchange, where during the season of navigation coal, ore and ship chartering are freely traded at the noon hour in the halls, offices and dining room. Buyers and sellers get together and all that is lacking to make the picture a duplicate of the daily gathering Mr. Wooton describes at Newcastle-on-Tyne is a statistical record of the business done or a blackboard on which to post sales.

Now, coal is bought and sold in this country in greater volume than in Great Britain. At Chicago, Cincinnati, Pittsburgh and perhaps other centers doubtless more tonnage of coal is traded in than on the largest British exchange, but here without the open marketplace. How is it done and why has the exchange never come into vogue? Certainly not because of legal inhibitions, for we have exchanges in other basic commodities, as sugar, cotton and wheat. Some reason doubtless exists in the natural disinclination of the coal trade to do anything different or new. But the main reasons for sticking to the present system of trading in coal are the efficiency of our telephone and the large bulk of contract business done.

The modern private telephone exchange is for a coal

company as the coal exchange is to the Englishman whose telephones are nowhere nearly as quick as ours. The best equipped companies have young men for the leg work of calling on the trade, but the office telephone is the mainstay of business.

It might be added that the only buyers that might be expected to attend a trading exchange in this country would be other coal traders; consumers are so accustomed to being besieged by salesmen in person, over the phone and by mail that they would have slight interest in the initiation of such a market place.

It is obvious that the coal trade would be much better off were it to have some reliable, up-to-the-minute record of sales and prices other than that afforded by gossip. The problem of the business papers reporting the market would be simplified thereby, it is true, but that can hardly be advanced as an argument for a revolution in the free and easy business practice of our coal traders.

"The First Robin" Is The Same Robin

WITH such a caption the Central Pennsylvania Coal Producers Association in a recent bulletin discusses the outlook as respects labor and wages. The statement which is carried in full elsewhere in this issue, notes that whereas in former times, discussion of wage agreements began with joint conferences of miners and operators, now it starts by conferences at the White House, where John Lewis and Secretary of Labor Davis call on the President, and by "dire predictions of strikes" emanating from the non-union operators. It is further noted that the union coal operators have not been consulted as to their necessities.

Then follows the advice to the United Mine Workers that they should understand that unless they help to establish conditions in the union fields permitting their employers to meet the competition of non-union operation, they will suffer lack of work even as the mines in which they work will suffer lack of market. It is prophesied that the union fields will become the "uneconomical" units of the soft-coal industry, doomed to go. The present competition from non-union areas adjacent to Central Pennsylvania is stressed and reductions in wage below the present 25 to 35 per cent cuts are prophesied as soon as the "union coal operators have been safely signed, sealed and delivered by another agreement." Criticism of this opinion is invited.

Now there is no gainsaying the fact that if and when the union fields renew their present scale, then will it be in order for the non-union fields to put general wage cuts into effect. So far they have held their ranks remarkably well, but the leaders of the South are finding it increasingly difficult to maintain that position. The protestations of union operators that they have concrete evidence of extensive competition from non-union coal at lowered cost indicates that the good resolutions of non-union operators are already dissolving.

The basic plea made by Central Pennsylvania oper-

ators is that their union miners give heed to the economics of the situation, face the fact of non-union wage reductions in effect and in prospect, and consent to meet those cuts by a reduction in labor costs of producing coal in that field. This has been put forward in the face of resolutions from the union locals demanding the 30-hour week and a 20-per cent increase in wages.

The statement of the case, therefore as far as Central Pennsylvania is concerned, is not new; it is 1922 over again. It will be remembered that John Lewis then answered that he did not propose to enter a competition with the non-union fields in wage cutting, that in such a contest the union areas would always be a lap behind and hopelessly outclassed. He therefore in 1922 elected to stand pat and the record of his success is clear. There is nothing to indicate that he has changed his policy or that he would be less successful in 1924.

The loudest talking is being done by those operators who, even though they may not want to have a strike, require that there be one, realizing that it will save them financially and by those in the United Mine Workers who are opposed to the Lewis *régime*. Central Pennsylvania is sore pressed, will be even more heavily pressed with a continuation of present conditions and knows not where to turn for relief, save to appeal to the men to be reasonable, face the facts and consent to join with the operators, their partners in business in meeting the situation.

It is then not difficult to agree with the general tenor of Central Pennsylvania's statement of the case, but it must be asked in return, what it proposes to do in the event that the union will not amicably consent to wages being so reduced as to meet non-union competition. Lewis is strong enough, it is believed, to get from his union a renewal of present wage scales but who has any idea that, no matter how he personally feels, he is, or will be, able to get the union to agree to a reduction? Hence how can there be thought of reduction without thought of a trial of strength?

We have no criticism of Central Pennsylvania's statement of opinion, but we do ponder what the answer may be.

Protecting the Buyer

ALBERTA has put into effect a real coal act. Even before Pinchot began dabbling in coal regulation the Legislature of Alberta passed (April 21, 1923) a Coal Sales Act that in September was made effective in all its provisions. Among other things ordered in this law are the branding of all coal by registered name, the requirement that operators and dealers display the name of the coal, its origin by mine, the district, size, grade and quality, when shipped and destination. Inspection is authorized at any time or place by properly designated officials.

From this it may be gathered that the purpose of the act is not to regulate prices, direct distribution, punish profiteers, prohibit resales, require publication of cost, prices, wages, profits and what not—in other words not a so-called fact finding measure. Rather the purpose is to protect the buyer by making it possible for him to know whence came his coal. That seems to be something heretofore overlooked by the legislation drafters in this country, and we commend it to their attention. A few more provisions to the proposals already formed may not break the camel's back.

There is another provision in the Alberta act that is sensible—that it is effective only until May 1, 1924. The lawmakers may have conceded that they were experimenting and agreed to make the sentence short for the coal man.

Are You Watching for Crop Fires?

AT ALL times the mines are subject to the menace of coal crop fires. In the summer forest and clearing fires are apt to ignite the coal through crop holes, the embers from the fire often falling through crevices and large openings in the roof and coming in contact with the coal. In other cases fires in slate piles and coal storages are likely to be communicated to an underlying or neighboring seam. Even the most harmless of slate piles are in the bituminous regions likely to burn, for all the slates in the coal measures are, in a degree, oil shales. That they are free of actual coal is no assurance that they will not ignite and burn into what is now known as "red dog." Ashes from boiler houses and from blacksmith shops also are a possible menace. The fact that they are not located near the particular seam being worked affords no security if they are near another seam, for a fire well started is not necessarily confinable to a single bed and a fire in a lower seam may make mining in an upper one impossible.

Managers of mining properties will do well to keep a watch on adjacent lands because fires started on these properties may extend to their own and the parties owning these lands may be little concerned as to the possible firing of the coal and in most cases may be too poor to make an adequate attempt to extinguish a fire when once started. Fires have been initiated, as Henry Phythyon has shown, by the burning of garbage. Possibly the persons starting them had an expectation that exposed coal either in the solid or thrown out of the hole would aid in sustaining the heat of material naturally disinclined to burn. They little thought that the small fire they started might devastate many acres.

The Bitner fire, that of the Youghiogeny & Ohio Coal Co. with that in the residential portions of Pittsburgh may serve to remind the public of the difficulty experienced in extinguishing such fires. Many shallow fires, especially in the anthracite regions, have cost millions of dollars. It is only necessary to refer to that on Summit Hill and to one which before it is extinguished may be equally costly—the Red Ash fire near Wilkes-Barre. One is likely to look upon shallow mine fires with less interest than those in the heart of a mine but they are apt to be far more expensive before they are quenched, if such extinguishment is ever ultimately achieved, as is to be greatly doubted.

The report of James Archibald, mining engineer and agent of the Girard Estate, mentions three fires in mine breaches caused by the ignition of rubbish, two at Kehley's Run Colliery and one at Packer No. 4 Colliery. Fortunately they were extinguished promptly. An ash-bank fire also occurred in the same year, 1922, at the William Penn mine. Discovered in August of that year it is said to be under control. The mention of these fires in the annual report of the Girard Estate is evidence of the importance that this estate lays on this possible form of destruction. Extinguishment of all crop fires is an essential part of any company's conservation program and one not to be dismissed with indifference, even if outside its immediate holdings.

*Equipment for Forging and Tempering Cutter Bits**

Correct Forging and Tempering Methods Double The Life of Undercutting-Machine Bits

Each Crew Carries Its Own Bits, Receiving and Delivering Them Through a Checking Station—How Cost Records Are Kept—Three Men in Turn Forge, Grind and Temper Each Bit

BY ALPHONSE F. BROSKY
Assistant Editor, *Coal Age*, Pittsburgh, Pa.

DISSATISFACTION caused by soft and brittle cutting-machine bits disgusts machine men and prevents them from cutting the scheduled yardage, thus upsetting the loading and haulage schedules of the mine. At the Lynch operation of the United States Coal & Coke Co. 1,800 cutter bits are given a correct shape, a sharp point and a correct temper every working day and only three men are employed in this service. Since the tempering has been made painstakingly and systematically the work done by each bit has been doubled. But before coming to that let me explain how the crews get their bits promptly and in accord with their needs, for at many mines that we know bits often go astray or arrive in inadequate numbers, and in consequence places are not cut. When men cut at night a little uncertainty or discouragement sends them home early to their beds.

Adjoining the tool room at the entrance to the machine shop at the Lynch mines is a station in which a record is kept of the cutter bits to be sharpened and issued each day. This system has been introduced for the purpose of preventing the machine runners from disturbing the bit sharpeners. After cutting their places the machine crews bring out their dull bits in regulation army canvas knapsacks and on their way to the bathhouse stop at the bit station to check them

in. The attendant, who also has duties in the tool room, places a check on the bag and gives a corresponding one to the miner.

This system has several advantages over the customary manner of handling bits. Foremost among these is the assurance given to each crew that it will have sharp bits, as one member of each crew carries to his cutting machine a sufficient number of bits to last one shift. Furthermore, bits are thus handled by but one man from the check room to the mine face, and he is the man most interested in their safe arrival. Moreover, with this arrangement the services of a bit boy are not needed. In some mines locomotive crews and mule drivers have to pass the bits from hand to hand. In the Lynch mines they are relieved of that responsibility, and hence are not delayed in the performance of their regular duties. Haulage is too vital a responsibility to be held up by giving motormen and drivers the duty of delivering bits to working places.

The man who sharpens the bits notes the check number on each knapsack and counts the number of bits it contains, entering the figures in a book provided for that purpose. He also records later the number of sharp bits placed in each bag. The form sheet used for this purpose is illustrated in Fig. 1. Sharpened bits are returned to the bit station ready for distribution and in each bag are placed sharp bits equivalent to the number of dull bits it contained when the crew to which it belongs brought it to the bit station. Where

*A forging machine, a good furnace, two steel tables, two sand boxes, two oil baths, three men and a well scheduled process provide each day for the machine crews 1,800 cutter bits that are really sharp and honestly tempered.

FIG. 2

DAILY RECORD OF DISTRIBUTION AND MONTHLY RECORD OF COST OF REPOINTING CUTTER BITS

Each day machine crews are provided with one sharp cutter bit for every dull one they turn in. Tally is kept of the transaction in the form shown in Fig. 1. Daily cost of sharpening cutter bits for each mine is kept form depicted in Fig. 2.

no records are kept the crews on cutting machines frequently are discontented, for at times they do not receive the number of bits they need for their work. If a crew turns in sixty dull bits it expects that number to be returned. When a machine runner or his helper calls in the evening for his bits the attendant in the station fills in the two right-hand columns of the record form—the name of the machine man and the section of the mine in which he works.

Cost figures on the sharpening of bits are kept by the man in charge of the bit station. By a knowledge of the time spent by the men engaged in sharpening he is enabled to ascertain a labor charge for each bit and to allocate the total cost of labor to each mine. This account he keeps in a record book in the form shown in Fig. 2. From each crew he gets information as to the number of places cut during each shift. It is a simple matter to figure the cost and to determine the average number of places cut for each set of bits.

The labor cost of sharpening is kept separate from that of making new bits. These latter are formed from bars of special tool steel, cut to length in a shearing

machine. The labor cost of making new bits is charged to supplies, and the account is handed to the supply clerk. As the machine runners must get new bits from the supply room, an accurate record of the cost of new bits (material plus labor) may be kept. A supply of 400 to 500 new bits is held for current replacements.

Three men are employed in the processes of shaping old and new bits. One man heats and forges them in a bit-sharpening machine, another grinds the upper surface of each and a third does the tempering. By dividing labor in this manner, better results are obtained, each man becoming more skilled in his work than he would be were he to perform all three processes. In either case the number of bits that must be sharpened each day at the Lynch mines requires the services of three men.

Heat for forging and tempering is derived from a single coal furnace, detailed in Fig. 3, and shown also in the headpiece of this article. Air draft can be furnished to the furnace either by an individual blower or else by a feed line from a central blower which supplies air to the blacksmith forges. The individual unit is preferable, of course. In the front of the furnace are eight ovens each of which is big enough to accommodate eight bits.

Four holes are used for heating the bits that have to be forged and the remaining four holes are utilized for tempering purposes. Wide-mouthed prongs serve to handle a set of eight bits at one time. In the process of forging, the bits are withdrawn from the fire one at a time and in regular rotation. The air blast is regulated to maintain in the furnace a temperature high enough to give the correct heat to each bit in the time required to complete the forging of 32 bits (eight bits in each of four ovens). This constitutes a cycle. A uniform temperature in the furnace imparts the same

FIG. 3—HEATING FURNACE FOR FORGING AND TEMPERING CUTTER BITS

This coal furnace closely resembles a gas furnace in that its design is such as to cause the flames to shoot out of the fire openings where the cutter bits lie. The latter do not come in contact with the coal.

heat to bits that are tempered as is given to those which are forged. Satisfactory results are obtained by this arrangement.

Where the degree of hardness required for the cutting of a certain coal is such as can be obtained only by heating the steel to a temperature higher or lower than that required for forging, I would suggest that a firewall be built to divide the furnace into two compartments. Then each compartment can be fired separately, and the draft in each regulated by an individual valve in each of the arms of a Y-connection from the main line.

After the bits are forged, they are cooled, and then ground on their upper surfaces so as to remove the scale of oxide which forms on the steel in the forging operation, thus providing a fresh metallic surface on which the man who does the tempering can better observe the manifestations of color when the heat is being drawn out of the steel. The following is a description of the heat-treating process:

Eight bits are stacked side by side to form a set, and staggered so that the tips of four of them alternately project about $\frac{1}{4}$ in. in advance of the four remaining bits. Four sets are placed in the four ovens provided for the purpose. One set of eight bits is removed from the fire upon being heated to the correct temperature. The eight bits as a unit are quenched in an oil bath for a sufficient length of time to reduce the heat to the desired temperature.

GETTING THE CORRECT TEMPERING HEAT

This time is gaged by observing the color of the oxide forming on the bit. The set of bits, grasped in a pair of prongs, rests on a metal-covered table during the observation period. The correct degree of tempering is indicated by the appearance of a filament of blue oxide which forms progressively toward the tip of the bit in the zone of tempering. The staggering of each set makes it easy to remove one or more bits without disturbing the others if it is manifest that they have not received proper treatment.

Uniformity of hardness in the zone of tempering is obtained by burying the tips of the treated bits in sand. An equalization of temperature is obtained in this manner without annealing them to a point where they are soft. Too great a degree of hardness, caused by too rapid cooling, is manifested by the appearance of a straw-colored oxide in the tempering zone.

Bits rejected because they have been overtempered are allowed to cool and later treated again. Those that are undertempered are further treated in the oil bath before they are buried in sand. An average of about one bit for every set treated is rejected for further treatment. After being cooled, all are removed from the sand box and inspected. Any that appear to have been overtempered or undertempered are grasped individually in a pair of blacksmith tongs having a small mouth, and the tips are struck against steel. When undertempered the tip will show its degree of malleability by bending over; when overtempered the tip of the bit will show that it is too hard by breaking off.

Three men will repoint about 1,800 dull bits in one shift at an average cost of 1c. per bit. The cost of pointing a piece of bar steel to form a new bit is $1\frac{1}{2}$ c. Since the institution of the tempering process at the Lynch mines a set of cutter bits on a shortwall cutting machine will cut, for each sharpening, twice as many places as before.

How to Minimize Breakdowns Of Electrical Machinery

Importance of Cleanliness and Regular Lubrication—
Bearings Should Be Kept Cool and Renewed
Promptly—Replace Fuses Carefully

By C. H. S. TUPHOLME

London, England

THOUGH breakdown of electrical machinery often can be traced to some cause quite outside the operator's or engineer's control, there are many instances where a little more care or a little more skill on the part of an attendant would have averted a breakdown. It is therefore necessary that every engineer in charge of electrical equipment see that the men under his supervision are thoroughly well trained in how to handle and care for the equipment.

In the first place, cleanliness is most important. All electrical machines and apparatus should be kept scrupulously clean, dry, and free from oil or dust, particularly copper and carbon dust, which are the most frequent causes of breakdowns of electrical plant. Oil rapidly destroys many of the materials commonly used for insulating purposes, while films of copper or carbon dust form conductive surfaces capable of short-circuiting the parts between or upon which they lie.

The parts of generators and motors requiring most attention are the insulating washers and bushings of the brush rigging, the inside surfaces of hollow commutators, the spaces between the end connectors of armatures and between the commutators and the armature cores inside the end connectors, and the insulating rings at the bearing end of the commutators.

PROTECT INSULATION FROM DETERIORATION

A fairly stiff brush and a pair of bellows, or better still, a blast of compressed air, will be found useful for removing dry dust and dirt. If oil is mixed with the dirt, a little gasoline may be used, and the parts thus cleaned should afterward receive a coat or two of good insulating varnish. Generators and motors should be dismantled at least once a year and thoroughly overhauled and cleaned; the windings should be revarnished.

When filling the oil wells in the bearings, great care should be taken to prevent any overflow. Every oil well should have an overflow pipe and drain tap, and every enclosed machine should have a drain pipe at the lowest point of the casing. A good quality light engine oil should be used, and it should be renewed or filtered from time to time. When renewing the oil, clean out the bearings and oil wells before putting in fresh oil. Always see that the oiling rings revolve freely after the machine has been started.

CARE OF BALL AND ROLLER BEARINGS

If the machine is fitted with ball bearings a good quality neutral grease is the best lubricant. Under ordinary conditions, with the ball races filled with a suitable grease, the bearings will run for several months without further attention, unless they are exposed to excessive dirt or dust. Do not put too much oil into the oil wells nor force too much grease through the ball races. Oil or grease will get onto the insulated parts of the machines, and deterioration and damage eventually will result. The proper amount of oil or grease put on a bearing will last a considerable time, and it is

unnecessary to be continually adding fresh lubricant when ring oilers or ball bearings are used.

Bearings should be renewed as soon as they show appreciable wear. This is especially necessary in the case of alternating-current motors, where the clearance between the stationary and revolving parts is very small. Comparatively little wear of the bearings will cause these parts to come into contact and cause serious damage. In the case of a hot bearing, fill up the oil well. If possible, keep the machine running slowly until the bearing has cooled. The heating may be due to lack of oil, a tight belt, dirt in the oil, or a bent shaft. All contacts and screw connections on machines, backs and fronts of switchboards, switches, fuse blocks, and other electrical equipment should be periodically tightened and kept perfectly clean, as heating at loose or dirty contacts is a frequent cause of fire and variations in motor speed and supply voltage. This, however, should be done only when the power is cut off.

When the intersegment micas are undercut the grooves thus formed should be kept free of dirt and dust. Carborundum cloth or sand paper may be used for smoothing the surfaces of commutators and slip rings if these should become roughened by sparking. If the commutators or slip rings are out of true, or if bad flats have formed, they must be turned true.

The following are the principal causes of sparking:

Direct-Current Machines

- (a) Overloading.
- (b) The brushes may not be set at the best position for sparkless commutation. In the case of machines having interpoles, a very small difference of position may cause considerable sparking, and in addition has a marked effect on the voltage regulation of a generator and the speed of a motor.
- (c) The various sets of brushes may not be equidistant from one another.
- (d) The brushes may not be of the right quality.
- (e) The brushes may not be free in the holders.
- (f) The brushes may require fitting to the commutator.
- (g) The brushes may not have sufficient pressure on the commutator.
- (h) The commutator may be rough, dirty, oily or out of true.
- (i) Vibration of machine, owing to faulty foundations or drive.
- (j) There may be a break or open circuit on one of the armature coils. This causes bad sparking and the burning away of the mica insulation between those commutator bars to which the faulty coil is connected.
- (k) One or more of the armature coils may be short-circuited. This causes overheating and burning of the insulating material of that particular coil.
- (l) The intersegment micas may be too hard, and therefore projecting beyond the surface of the copper.

Alternating-Current Machines

- (a) The brushes may not be of the right quality.
- (b) The brushes may not be free in the holders.
- (c) The brushes may require fitting to the slip rings.
- (d) The brushes may not have sufficient pressure on the slip rings.
- (e) The slip rings may be rough, dirty, oily or out of true.
- (f) There may be excessive vibration.

The fuse is the safety valve of an electric circuit. If a fuse blows after having been properly adjusted, the supply should be shut off, the contact surfaces and binding screws or the fuse blocks should be cleaned, and a new fuse, of the same size as the old, put in. Should this blow there probably is a ground or short-circuit

on the system. On no account should a fuse that is too large to give proper protection be substituted.

In replacing a fuse care is necessary to neither stretch nor otherwise injure the wire when attaching it to the terminals, and also to see that good and clean contact is made between the wire and the terminals. If this is not done local heating will take place, in which case the fuse will melt at a lower temperature than it would otherwise.

Copper strips or wires make very reliable fuses, but for very small currents—say below 14 amp.—tin composition wires are more suitable owing to their being more convenient to handle. For large currents—say over 100 amp.—it probably is better to use some form of mechanical-overload circuit breaker.

As a general rule every circuit should be protected by a fuse or other circuit breaker, which will open the circuit with a current not exceeding double the normal full load. In many cases it is not advisable to allow so great a departure from normal working conditions, while in exceptional cases a greater margin may be permitted.

In the case of alternating-current motors of the squirrel-cage type, which may take from three to six times the full load current at starting, the connections should provide for the normal fuse being temporarily shunted or out of circuit during the period of starting. The type and form of the fuse holder has considerable influence on the efficiency and reliability of the fuse as a circuit breaker.

KEPT TOOLS AWAY FROM DYNAMOS

As many breakdowns have been caused by foreign bodies falling or being drawn against revolving armatures by the magnetism of the field, or otherwise, attendants should be cautioned not to use the tops of machines as tables, nor to have steel or iron tools, or oil cans near electrical machines. Copper oil cans are preferable to those of iron or tinplate. The tops of switches, starters, controllers, and resistance frames or boxes also should be kept clean and not be used for placing loose articles.

In starting direct-current motors care should be taken to move the switch arm slowly across the contacts of the starting resistance, in order to prevent the armature receiving an excessive current while getting up its speed. The contact studs of the starting switch should be kept clean and smooth. Deterioration, from corrosion, of the resistance coils in connection with a starting switch when mounted in a damp location may be prevented by the application of one or two coats of a good moisture-resisting enamel. Immediately after starting up a generator or motor the attendant should see that all bearings are being properly lubricated and that the oiling rings are revolving properly.

Before switching current onto any motor, care should be taken to see that the handle of the starter is in the "off" position. In the case of a direct-current motor, if a shunt regulator is used all resistance should be cut off at starting, while in the case of a direct-current generator with a shunt regulator connected, all the resistance should be in circuit at starting.

After a generator or motor has been installed and connected up, a diagram, plainly showing the actual connections, should be made and hung up near the machine. Such a diagram will often save much time in the event of any trouble with the machine or starting equipment.

John C. McNeil Describes

More Short-Line Ways of Handling Coal Sales

Accounting Is Not Writing a History of Past Transactions
So Much as Recording the Immediate Status of Accounts
In Order to Afford a Basis for Decisions as to Credits

ALTHOUGH modern methods of mining have superseded the old way of the pick miner, and the "hay-burner" has given way to the electric mule in haulage, archaic methods still seem to prevail in the office.

The principal object of any accounting system is to serve the management as a guide by which to direct future operations, and if the system is a history, rather than an up-to-date statement of facts, it is useless for any such purpose. Pen-kept records cannot be kept up to date like machine methods, and the time required at the end of the month to prepare the statements for customers, make up the payrolls, pay off the bills and render the necessary statements to the management and the owners is so long that before the statements are out, another month is upon the office force.

The underlying principles of machine accounting are the same as those in other methods, with the addition of controls and proofs not obtainable under the old pen methods of accounting. Ledgers are kept in balance and up to date, so that it is possible to take off a trial balance of the accounts or to render a statement which is in exact balance with the ledgers at any time.

EVERY RE-ENTRY AN OPPORTUNITY FOR MISTAKE

Take, for example, the pen system of handling accounts receivable. After a car of coal is loaded at the mines a bill of lading must be made, and after the coal has been weighed the shipment must be entered in the shipping record. An invoice is then made up, either from the bill of lading or from the shipping record. If the invoice is made from the bill of lading it is used as the posting medium for the shipping book or if the invoice is made after the shipping book is written up, this book becomes the posting medium. After the invoice is mailed, entries are made in the accounts receivable ledger, using either the invoice or the shipping book as the posting medium.

At the end of the day, or period of operations, sometime at the end of the month, the shipping book has to be totaled and balanced, the accounts-receivable ledger accounts totaled and balanced, statements taken therefrom covering each account, added and balanced with the ledger. In order to keep the end-of-the-month peak load down to the limits of human endurance, the usual custom around coal-mine offices is for the bookkeeper or his assistant to keep posting statements from time to time during the month so as to have them ready at the end of the month for mailing to customers.

As it is of the utmost importance to get statements of accounts receivable out on time it is almost the invariable custom to mail these statements before the general ledgers are balanced. Should the accounts-receivable ledger be out of balance with its control at the end of the month nothing can be done other than

to adjust the control to agree with the statements mailed to customers.

By the short-line methods hereinafter described, the work of the coal-mine accounting office is shortened, the invoice being made, the ledger being posted, the customer's statement being prepared and the sales or shipping record being made at a single operation. At the same time by using machine accounting the balance due from each customer is calculated down to date, showing these balances on his ledger account and statement as well. So at the end of the month, there is nothing to do but mail the statement to the customer. This can be done just as soon as the invoices for the last day of the month are made out.

EVERY MONTH BEGINS WITH OVERTIME SHIFTS

Accounts payable at coal mines are either handled through the voucher system, or through the use of an accounts-payable ledger, and sometimes through a combination of the two. Under the former system accounts-payable invoices are accumulated at the end of the month, vouchers drawn for them and then entry is made in the voucher register distributing accounts.

Under the latter, invoices are entered in invoice registers and postings made to the accounts-payable ledgers. Statements are then taken off for remittance advices, entries made in the cash book of checks drawn and then the cash entries are posted to the accounts-payable ledger. Under either plan of operation the end of the month brings long working hours to the office force, working under strain, and the accounts-payable liability is not known until all of these entries have been made. In the short-line method described herein these accounts are posted, voucher or remittance advice made and distribution is made at the same time, with an additional knowledge at the end of each day of the exact amount of liability.

The archaic method is a costly one and aside from the delays and peak loads, expense is an item to be considered.

As previously explained, the chief advantage of machine accounting is having the ledgers always in balance and the general ledger entries up to date. The advantages of machine accounting are based upon the same principles that have enabled undercutting machines and haulage motors to effect savings in time and labor. This system was designed with the idea of saving time and labor as well as having accurate accounts, legibly written and the maximum of work done at one operation.

Accounts Receivable—The system of dealing with accounts receivable has already been described in detail in my article entitled "Machine Bookkeeping Speeds Accounts at the Mine," which appeared in *Coal Age*, Aug. 30, pp. 319-322. Reference therefore is made to that article. The forms given on page 321 as of the General Coal Co. do not cover errors arising from charging the wrong party, over- or under-charging, allowances for defective preparation, prepayments of

This article by John C. McNeil precedes one on handling of expense accounts, payrolls and the general ledger. It should be read; in connection with the article in *Coal Age* of Aug. 30, 1923, pp. 319-322.

freight and so forth. For these reasons have been added Forms Nos. A-7, A-8 and A-9. For the forms Nos. A-1 to A-6 see the article in question.

Often coal is shipped to prepay stations, necessitating the prepayment of freight charges, which of course, are chargeable to the customer. A debit memorandum is made against the customer on Form A-5 with the proper explanation. This is at the same time posted on Forms A-2 and A-3, "Accounts Receivable Ledger," and the "Customer's Statement," and in addition is entered on the "Sundry Accounts Receivable Debit Sheet," Form A-8 as a proof of accuracy and for General Ledger charges. These debit memoranda should be entered at one run, as illustrated on the few postings shown on Form A-8. Credit distributions are entered on these sheets and after postings have been completed the items will balance as shown on the form illustrated.

CREDITS TO ACCOUNTS RECEIVABLE SHEET

Credits to Accounts Receivable are through cash payments made on accounts by customers, Notes or Trade Acceptances given and Credit Memoranda. For this reason one Credit Sheet, Form A-9, "Credits to Accounts Receivable," is used and on this sheet is posted the appropriate data, using as before, at the same time Forms A-2 and A-3, Accounts Receivable Ledger and the Customer's Statement. Allowances to customers should be made through the medium of Credit Memoranda, Form A-6, which should be used in connection with the account forms described, viz.: A-2, A-3 and A-9.

The cashier should prepare, for the operator, cash posting slips for all cash postings, note slips for notes and trades acceptances and other authorities should prepare the data for the allowances. Predetermined totals should be taken of these items, so as to prove the accuracy of the work after postings are made. Postings to the General Ledger from these sheets are made in the same manner as from the Sales Sheet.

Under this system it is next to impossible to post an entry to the wrong account. If an invoice is made against the Brown Coal Co. the operator must also have the Brown Coal Co.'s statement and Ledger Sheet. However, should such an event occur, we have provided for that by the use of Form A-7, "Journal of Accounts Receivable Inter-Account Transfers." The Customer's Statement and Accounts Receivable Ledger should be posted in connection with this form and the total debits will equal the total credits on this form, which after completion should be posted into the General Ledger.

It will be seen from this description that it is not possible to make an entry in what is usually known as the books of original entry without also entering the amount in the ledger and on the customer's statement at the same time. In other words, the ledger and statement become as much the book of original entry as the journal.

Balances of each ledger account are taken after the completion of each entry and by the keeping of a control account in the subsidiary ledger to which totals are posted after the completion of each Journal or Proof Sheet, the operator can ascertain at once the total balance due on each account and as well on all accounts. In addition to this, an adding machine run of these accounts will prove with the total balance as shown by the subsidiary control sheet. This subsidiary control sheet will likewise be in accord with the control account kept in the General Ledger.

A complete account with different kinds of entries is shown, both as to statement and ledger account—see Forms A-2 and A-3, as an illustration of how they are worked. Under this short line system, the customer's statement is ready for the mail at any time. At the end of the month, when statements are ready to be mailed out, new statement sheets are headed and the last balances shown are entered as an item brought forward to the new statement. A proof sheet is kept in the machine which will be used as a trial balance or statement of balances due by customers. The total of this statement will agree, of course, with the balances shown in the "dummy" and general ledger controls.

Accounts Payable.—The usual method of handling accounts payable is either through a voucher system, making the vouchers direct from the invoices at the end of the month, or through an accounts payable ledger, posting credits and charging checks or other items. Either system requires a vast volume of work and incurs the ill will of the office force through the peak load at the end of the month.

ACCOUNTS PAYABLE VOUCHER SYSTEM

It being customary with coal companies of any standing to settle their accounts monthly on a cash basis, taking whatever discounts are necessary, they are not interested in an accounts payable ledger, showing debits and credits to creditors, together with the attendant labor of debiting these accounts with cash payments, discounts, etc. The principal object to be attained under this method is to see that all payable invoices are accounted for, that the creditor receives credit for his invoices and that a remittance slip is given showing the invoices paid. Other than that an account is not necessary, nor is it wanted. We have provided, therefore, under our short-line method for an Accounts Payable Voucher system instead of a ledger.

Invoices when received from creditors should be entered in a memorandum book of some nature by the accounting department, showing the date, name of creditor, amount and to whom referred. It might be well to number these entries beginning at the first of each month or at the first of each year, as desired by the accounting official. After the invoices are approved by the department receiving the goods, they are sent back to the accounting department, checked off this list and arranged in alphabetical order. A predetermined total is taken of these invoices, as was described for the accounts receivable entries. After this total is taken and entered in the chief accounting officer's memorandum book, they are handed to the operator for posting.

Form B-1, Journal of Accounts Payable Credits, is placed in the machine and Form B-2, Accounts Payable Voucher (in duplicate) is used. On the voucher is entered the invoice number (ours), date, amount of credit and new balance. This is automatically entered on Form B-1 at one operation and the distribution to the various accounts effected at the same time. It will be observed from the sample form herewith that the total charges to the distribution accounts will equal the total credit to accounts payable.

The total of the old balance column, plus the new credits, will equal the balances shown in the new balance column. After the invoices are entered on this sheet they should be cancelled as entered or credited to accounts payable, together with the date, and the journal page number and then filed away alphabetically. The voucher and its duplicate should be kept in the current

file for audit purposes. Credit memoranda issued by creditors should be posted on Form B-3, Journal of Debits to Accounts Payable and the proofs of posting on this are the same as on B-1.

When the accounts are due for payment, the voucher should be taken out and the invoices lifted from the alphabetical suspense file for audit purposes. The audit can be made by checking each of the items shown on the remittance advice. Form B-4 should now be used, filling in the check. The amount of the last balance shown in the balance portion of the remittance advice should be repeated on the check portion on the line "Amount of last new balance," the number of the check written in, the name of payee, the amount of discount to be taken on the total remittance and the machine will automatically calculate the balance, which is the net amount of the check.

The date of issue should next be written in. This will automatically make the check register, showing the total debits to Accounts Payable, total credits to discounts on purchases and total credit to the bank. After this is done the voucher and duplicate should be separated and the invoices covered by the voucher should be firmly stapled to the duplicate voucher and filed in the paid file alphabetically. This file will then give the invoices covered by any particular payment to a creditor, the date and number of check issued thereon, the amount of discount taken and the net balance due. The payee will of course, keep the remittance slip for his files and after the checks are returned by the bank and reconciled, they should be filed in numerical order.

Subsidiary and General Ledger controls should be kept on these accounts and the total of the vouchers remaining in the open file will agree at all times with the control figures.

Pressing Water Out of Peat

WATER is not readily pressed out of peat, for it is not in that substance as "water" but as gel, just like the water in a jelly. Recently J. W. Hinchley, professor of chemical engineering at the Imperial College of Science and Technology, London, England, has discovered that extreme cold and heat destroy the colloidal matter which holds the water in the peat, so that the moisture can be reduced to 40 per cent or even to 30 per cent by the application of pressure. Unfortunately, extremes of heat and cold are said to destroy the binding qualities of dried peat blocks to such a degree that they fall apart.

A REPORT on the Twentymile Park district of the Yampa coal field of Colorado, just published by the U. S. Geological Survey, which was prepared by Marius R. Campbell, shows the outcrops of all of the more valuable coal beds or groups of beds and the location of mines and prospects, by which the outcrops are generally marked. Particular attention was given to coal beds of the middle and lower groups, for these are the only ones that are now being mined on a commercial scale. The object of the work was first to determine the number, thickness, continuity, and geographical distribution of the beds and the quality of the coal in each bed. When this was done it was fairly easy to correlate beds in distant parts of the district, to predict where workable coal would be found in each bed, and to make an estimate of the available tonnage of coal in each section of land in the district.

The Miner's Torch

Our Mining Villages

PROBABLY the most misunderstood institution in connection with the coal-mining industry, so far as the general public is concerned, is the company-owned town. In all of my experience I have never run across an outsider who could visualize, even by the wildest stretch of the imagination, a company-owned town as a necessity. Even the social workers from the cities who journey out to the mining camps, prompted by the best of motives, have a hard time "being shown" as it were, when the subject comes up for discussion.

Once during a strike when a company that I was with was getting a lot of cruel publicity from the daily papers because of tenant evictions, I got a reporter to come out to my office so that I could give him the story of our camp, which started with a virgin tract miles from the nearest railroad and with not a home of any kind within a day's journey. One of the company's biggest problems was to get money enough to build the town that was required and to stock the commissary with goods for which payment could not be collected until the newcomers had a chance to make a start.

The reporter had never thought of the matter in quite that light, but it made little impression on him and he could not sense an interesting story in anything that I told him, so my trouble was all for nothing. Before he got out of our camp he saw some families moving out, and the story that he wrote next day showed that he had taken in every detail of that event.

I was not with him when he saw the departing families, so I was not allowed to explain to him that unless we could get possession of our houses we could not begin mining again, and that if all the idle mines should remain idle there would be a shortage of coal, and of necessity much suffering would follow. But some of my fellow superintendents did make such explanations to newspaper men, and they might as well have saved their words, judging by results accomplished. The reasonable rent that the miners had been charged was a thing of the past; the coal famine that might come was a thing of the future; but today families were being forced from their homes with no place to go and that in spite of the promises and efforts of the union—there was *the* story.

The above relates to incidents that happened years ago, and I have long since become hardened to the taunts of foes and friends outside of the mining industry, but it has lately occurred to me that it might have been better for the industry today had I and all the other superintendents of a decade ago remained sensitive to outside criticism, even to the point of going around with chips on our shoulders. One need only follow the reports from Washington to realize that the law makers and the general public are gunning for the coal man—the misunderstood coal man, without a friend at court—and he is likely to be hit at any time and in almost any spot. Unfortunately, all of this feeling against the industry is coming to a head at a time when it is threatened with overproduction and vanishing profits. We may even have to witness the abandonment of many company-owned towns.

Features That Should Be Embodied in the Design of Plunger and Centrifugal Pumps

Pumps, Crescent Coal Co., Beaver, Ky.

Mining Congress Committee Suggests Standards Which Should Govern Construction of Pumps in Coal Mines, Not for Gathering Water but for Its Delivery to the Surface

WHEREVER possible, all permanent pumping stations should be so constructed and the pumps so placed in them as to allow at least 3 ft. of space all around each pump, thus providing that ample room shall be available to get at all parts of the mechanism when it is necessary to make repairs. The height of the station should be such as to permit of the use of the chain blocks whenever heavy parts have to be removed. Space also should be provided adjacent to the pumproom for the making of ordinary repairs. In the larger pumping stations a hand traveling crane should be installed, and one end of the pump station should be extended about 15 ft. beyond the floor space needed for the reception of the pump or pumps.

This additional length should be served by the same traveling crane, and where ordinary repairs can be made, extra parts should be conveniently stored. In the larger pumping stations a work bench with vise should be supplied, also cupboards or lockers furnished with substantial locks and keys where all wrenches, small supplies, etc., can be kept safely for the exclusive use of the regular pump attendants.

UNDER 200 GALLONS PER MINUTE USE PLUNGER PUMP

No hard and fast rule can be made specifying when plunger and when centrifugal pumps should be used. In general, however, it can be stated that when the capacity is less than 200 gallons per minute, a plunger pump should be used and when the capacity is 2,000 gal. per minute or over, preference should be given to centrifugal pumps. Between these two limits the deciding factors are the heads against which the pump must operate and the cost of power required to operate the pump. In Table I a tentative suggestion is given as to the type of pump to be installed where the power charge is 2c. per kilowatt hour.

Specifications for Plunger Pumps.—Pump purchasers should give the following information to prospective pump builders: The number of pumping units required, the capacity of each pumping unit in U. S. gallons per minute, the total head against which the pump is to operate (this total head to include suction lift and pipe friction), the suction lift from the floor of the pumproom to the level of the water in the sump, the

length and size of both the suction and discharge pipe; also the speed at which the pump should be run. This should not exceed 65 r.p.m.

The purchaser also should inform the pump builders of the name of the firm that will furnish the motor for driving the pump, as well as the current characteristics; namely, whether direct current or alternating current can be furnished and at what voltage, also the phase and cycle if alternating current is to be used. If the purchaser furnishes the motor it should be one running at the speed recommended by the pump builder, and he should deliver the motor, freight prepaid, to the pump builder for mounting on the base casting.

SECTIONALIZE WATER END FOR LOW REPAIR COST

Plunger pumps should be of vertical, triplex, single-acting, outside-packed plunger pattern. As far as possible the water end should be of sectionalized design, so as to minimize the cost of repairs, and it is recommended that the pump should be of the pot-chamber pattern, should consist of three interchangeable water cylinders, three discharge and three suction pot chambers, all three water cylinders to be interchangeable as well as all pot chambers. The water cylinder should be of cast iron and the stuffing-box throats lined with bronze bushings.

The water valves should be of rubber, resting on bronze seats, and, as before stated, each valve should be set in its individual cast-iron chamber and be provided with covers for ready access to the valves. The valve seats preferably should be of the flange type, bolted between the bottom of the pot chambers and their connecting branches. Where the water is acidulous it is recommended that the water cylinder, pot chambers and connecting pipe be all wood-lined. All water cylinders and air vents should be tapped and furnished with drain valves.

Plungers should be of cast iron, accurately polished. For acid mine water, however, they should be of hard bronze or preferably of porcelain. The plunger glands should be constructed of cast iron, and each be provided with four gland bolts.

The crankshaft and connecting rods should be of cast or forged steel and the crank and crosshead pins should be fitted with adjustable brass boxes. Crossheads should be provided with adjustable babbitt-lined shoes.

Single-reduction gearing should be used between the

TABLE I—PUMP EQUIPMENT FAVORED FOR VARIOUS HEADS

Capacity Gal. per Min.	100-Ft.	200-Ft.	Total Head			
			300-Ft.	400-Ft.	500-Ft.	600-Ft.
200	P or 1C	P or 2C	P	P	P	P
300	P or 1C	P or 2C	P or 2C	P	P	P
400	1C	P or 2C	P or 2C	P or 3C	P	P
500	1C	2C	P or 2C	P or 3C	P	P
600	1C	2C	2C	3C	P or 4C	P or 5C
800	1C	2C	2C	3C	4C	5C
1,000	1C	2C	2C	3C	4C	5C
1,200	1C	2C	2C	3C	4C	5C
1,500	1C	2C	2C	3C	4C	5C
2,000	1C	2C	2C	3C	4C	5C

Note—"P" signifies plunger pump; "1C," single-stage, double-suction volute centrifugal pumps; "2C," two-stage centrifugal pumps, or preferably two-single-stage volute centrifugal pumps in series; "3C," "4C," and "5C," three, four and five-stage centrifugal pumps, respectively.

motor and the crankshaft or pump. The pinion should be of forged, and the wheel of cast steel. All gearing should be furnished by the pump builder, who also should bore and keyseat the pinion to suit the motor shaft. All gearing should be protected by a sheet-iron guard so constructed as to be readily removed. The frame should consist of three vertical standards so arranged as to form outboard bearings for both pinion and crank shafts.

In pumps of larger size it is recommended that the gear pinion be mounted on an independent shaft supported by two ring-oiled babbitt-lined bearings attached to the two outer frames or standards, the motor being coupled to this jack shaft by a flexible coupling of the pin-and-buffer type. This flexible coupling should be furnished by the pump builder. He also should furnish a suitable cast-iron base plate for supporting the motor frames and pumps. The upper part of the standards or frame should form the main journal boxes which should be babbitt-lined and provided with all the adjustments necessary to afford a correct alignment in all three bearings in case any one bearing should be subject to excessive wear.

The pump builder should furnish a flanged iron water-relief valve set for a pressure exceeding that of the discharge by 50 lb. This valve should be bolted to the discharge pipe. Other equipment which he should provide are a 6 $\frac{3}{4}$ -in. dial vacuum and a 6 $\frac{3}{4}$ -in. dial pressure gage, grease cups for main journals, crank and crosshead pins, a revolution counter and a complete set of standard and special wrenches.

All castings should be clean and free from sand, dirt or blowholes. All parts proving defective in design, workmanship or material within a period of one year after the pump is received, should be replaced by the builder free of charge. All parts of the machine should be subject to the inspection and approval of purchaser's engineers, to whom full facilities should be given to test the pump at the factory under actual working conditions before the shipment is made.

Pump builders with their proposal should furnish purchasers with the net weight of pump complete but without motor and should submit with their proposal blueprint giving sufficient data to form an intelligent conception of the pump. The pump builder also should state the time required to furnish pump after the receipt of full information regarding motor and any other manufacturing details.

Specifications for Centrifugal Pumps.—The purchaser should give the pump builder the same information as has been advocated already in the specification of plunger pumps. The pump should be of the horizontal type with horizontal split casing, suction and discharge connections being on the bottom half of the casing and so designed that by removing the upper half of the pump casing the whole interior of the pump will be revealed and can be examined readily. The pump should be so designed that if for any cause its rotation is reversed in direction, the machine will not be damaged.

The pump builder should furnish a heavy cast-iron baseplate for supporting the pump and motor and should accurately align both and place dowel pins in the pump base so that it cannot get out of alignment.

When pumping fresh water the casing should be of cast iron; when handling gritty water it preferably should be of special hard iron; when raising acidulous mine water the casing should be of acid-resisting bronze. As it is readily understood that the pump builders cannot know the conditions under which each installation must operate as thoroughly as the purchaser himself, it is recommended that the purchaser specify the material from which he desires the casing to be constructed.

In order to minimize repairs, the casing should be fitted with renewable sealing rings, the same material

Three-Stage Pump

Workings at Orchard Slope, No. 1 Shaft. The subcommittee on permanent pumps advises that three-stage centrifugal pumps be used for 400-ft lifts when capacities of 600 to 2,000 gallons per minute are required and either a plunger pump or a three stage centrifugal pump for raising 400 to 500 gallons per minute. Some engineers prefer to use single-stage pumps connected in series so that the various units can be disconnected or connected to others and the pumps adapted to the various lifts with which they may have to contend when moved from place to place.

Four-Stage Centrifugal

At the mine workings of the Consolidated Coal Co., Saginaw, Mich. Large capacity, minimum horizontal and vertical space occupied and low cost are among the good qualities of the centrifugal pump, especially when installed to take care of the overloads due to sudden floods.

being used as in the casing. These should fit around all revolving parts, suitable provision being made to prevent the rings from turning. For this purpose the use of small screws or dowel pins should not be permitted. All high spots of the casing should be tapped and furnished with suitable cocks for air vents; also cocks should be furnished to drain the entire casing.

The impellers should be of the enclosed type, made of bronze and fitted with renewable bronze rings secured by a shrinkage fit onto the impellers, no small pins or dowels being permitted.

Stuffing boxes should be deep enough to take not less than four rings of packing after allowing the glands to project $\frac{1}{2}$ in. into the stuffing box. They should be provided with renewable bronze neck rings or bushings. Each stuffing box should be fitted with a "Lantern" gland, furnished with suitable bronze cocks, pipe and fittings for an outside water seal. Glands should be of bronze, made in halves and fit snugly in stuffing boxes, but be bored out $\frac{1}{8}$ in. larger than their shaft to prevent them from riding on it or rubbing it.

The pump shaft should be of open-hearth steel, of liberal proportions and protected at those parts which come in contact with the water by cast-bronze bushings made to project through the stuffing boxes and forming collars to keep the impeller in place laterally, the whole so arranged that in case of wear they may be readily renewed without destroying the main shaft. Provision should be made to prevent leakage along the axis of the pump shaft. This can be done by inserting fiber gaskets between all bushings and hubs of the impeller. The impeller should be secured direct to the steel shaft by a bronze key. The shaft with its impeller, rings and coupling should be perfectly balanced before being placed in the pump.

The pump builder should furnish all couplings, which should be of cast iron and as light as possible consistent with ample strength. They should be of the flexible pin-and-buffer or other approved type. The motor coupling should be bored and keyseated and should be fitted to the motor shaft by the pump builder.

All couplings should be guaranteed to run cool 24 hours under full load without water cooling. All bearings should be lined with the best grade of babbitt or with some other approved anti-friction metal; be split and accurately fitted to cast-iron boxes with bolted caps, the whole so arranged that bearings can be removed,

rebabbitted or renewed without disturbing the shaft or other parts of the pump. Each bearing box should form a liberal oil well and be provided with gage glasses that will show that oil is present when the base is full of oil. It also should be fitted with plugs for draining the oil. Suitable washers or collars should be fitted on the end of the shaft to prevent water or dust working into the bearings.

Except where the pump handles very gritty water or the water is extremely acidulous, it is recommended that all multi-gage pumps be of the hydraulic balance type or of the back-to-back construction. However, in some designs of pumps it is necessary to furnish a thrust bearing that will take care of the end thrust when the machine is being started as well as any unbalanced thrust which may occur in operation. If furnished, the thrust bearing should be of liberal proportions with all suitable adjustments and so arranged as to allow of removal or repairs without disturbing or destroying the main pump shaft. The thrust bearing should be enclosed, self-oiling and capable of running cool under a full-load run of 24 hours' duration, and, if desired, this bearing can be water-cooled.

SAFETY GUARD SHOULD BE PROVIDED

To protect the motor from injury due to pump leakage caused by the blowing out of a gasket or other packing, also to prevent the operative from being caught in the revolving coupling, a suitable sheet-iron guard should be furnished by the pump builder. The guard should consist of a vertical shield, of a thickness not less than No. 16 gage; should be the full width of the motor base and have a semicircular top and be placed around the pump shaft between the inner bearing box on the pump and the hub of the pump coupling, with a circular hood built on the back of the shield which will entirely encase the couplings; the whole being split vertically with halves bolted together and rigidly connected to the baseplate, but so arranged that it readily can be removed.

The inside of the casings and the impeller should be painted with two coats of Highland non-corrosive paint or of some other approved acid-resisting coating.

Each pump should be furnished with a water-pressure gage having a $6\frac{1}{2}$ -in. dial and with a vacuum gage of the same dimension. This should be mounted on a suitable board for fastening to the pumproom wall. Piping to connect the gages with the pump should be

furnished by purchaser. The pump builder should furnish all necessary fittings, air vents, drain pipes, circulating pipes for thrust bearings and all standard and special wrenches; in short, provide everything necessary for the satisfactory operation of the pump from its suction inlet to its discharge outlet.

All castings should be free from sand, dirt or blow-holes, and be smooth on the inside as well as the outside. All parts proving defective in design, material or workmanship within a period of one year after the pump is placed in actual operation should be replaced by the builder free of charge. All parts of the machine should be subject to the inspection and approval of the purchaser's engineers, to whom full facilities should be given to test the machine at the factory, as nearly as possible under working conditions, before shipment is made.

Bidders should furnish the price of pump complete, as specified without motor, the time required to furnish pump after receipt of full information regarding the motor, complete specifications with blueprint showing sufficient details to form an intelligent conception of

the machine offered, the efficiency of the pump when running under working conditions, the net weight of the pump complete with baseplate but without motor. If the manufacturer wishes to quote on a pump other than as specified, he should quote a price with full detailed information of its advantages over the pump specified.

In Table II the sizes of several important parts of centrifugal pumps having capacities from 500 to 8,000 gallons per minute are recommended.

TABLE II—RECOMMENDED DIMENSIONS FOR CENTRIFUGAL PUMPS OF VARIOUS CAPACITIES
(All dimensions are in inches)

	Capacity in Gallons per Minute

American Steam Shovel Nears North Pole

WITHOUT doubt the record for farthest north for American steam shovels is held by the one operating on the Spitzbergen Islands, off the coast of Norway. These islands lie north of the Arctic Circle between 76 and 81 deg. north. The coal mine farthest north is 79 deg. north latitude. Some of the coal deposits lie about 650 ft. above sea level, but at King's Bay the deposits are little above sea level. The coal is transported to the shore by ropeways. Here the coal is handled by means of a 36-in. gage railway which transports it to storage piles or to the loading pier. This railroad can boast that it is the northernmost in the world.

Fortunately for the coal operators the climate on the islands is comparatively dry, and hence the coal does not freeze hard. The coal is frozen in the ground and never thaws out. The difficulties are therefore in mining and not in handling after the coal is mined. Considering how far north it is, the thermometer does not show any great extremes, the mercury seldom registering below 15 deg. below zero. The harbors are cleared of ice about the middle of June and remain free of ice till the middle of September, when cold weather sets in.

The working days are long enough in the summer to suit the most exacting. The sun does not go below the horizon on Spitzbergen from April 20 to Aug. 24, and it does not come above the horizon from Oct. 26 to Feb. 16. However, the long night is not so dark as

might be expected, for the aurora borealis, which illuminates the landscape, is, of course, visible for the whole of the twenty-four hours when the sun is not above the horizon.

During the winter months the only means that the islanders have of communicating with the outside world is by the wireless that the Norwegian government has installed.

The largest operating coal company is the Store Norske Spitzbergen Kul Co. It has produced on an average of 60,000 tons annually. When the shipping season opens, the number of miners usually is doubled. As far as possible the coal from the mine is sent direct to the ships.

Production by the "Iron Man"

Tables have been prepared from which it is ascertained that in the mines of Great Britain in 1922 there were 5,434 coal-cutters in use. The number driven by electricity was 2,395, compressed air being the driving power for 3,039 of the machines. Although compressed-air coal-cutters are in the majority, their average production is much below that of which the machine driven by electricity is capable. The machine-mined coal last year amounted to 38,124,122 tons, which represents 15.2 per cent of the total produced, the average tonnage per machine working out to 7,015 tons. At the beginning of the present century only about 3 per cent of the coal was got by the "Iron Man." Even today the machine does not operate so extensively in South Wales.

Steam Shovel Near North Pole

Though the temperature is always low, and night and day are long seasons rather than mere diurnal divisions of time, the shovel handles stored coal without difficulty, for the frost is in the coal and does not bind the lumps or slack together.

British Coal Exchanges A Popular Form Of Co-operative Effort

Eliminate Senseless Competition and Clamor for Regulatory Legislation—Newcastle Exports Noted in 1325—Coal Age Correspondent Urges Organization at Norfolk on Old World Pattern

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

GREAT BRITAIN has escaped any wave of popular clamor for anti-trust laws and legislation calculated to prevent "restraint of trade." As a consequence, that country enjoys numerous advantages flowing from united action. The wastes incident to senseless competition in bituminous coal are eliminated and the vitality of the industry is not drained in the same way as is the case in this country.

Despite the absence of statutes comparable to our Sherman and Clayton acts, no condition has arisen to cause even a suggestion that the industry be subjected to regulation of the public-utility type. It is true that there has come from labor the entirely unrelated demand for nationalization, but the severe defeat of that proposal has so impressed the labor party that it probably will be disinclined to risk its hard-fought gains on an issue regarded as unsound by a clear majority of the people of the kingdom. It may be said, however, that the issue is by no means dead.

COAL EXCHANGES AN OLD CUSTOM

A popular form of co-operative effort in the United Kingdom is the coal exchange. Even our Federal Trade Commission, with its electrically propelled, radio-directed and thoroughly modernized muckrake, could find no fault with this institution. There can be no restraint of trade at gatherings of buyers and sellers.

Exchanges are maintained at the principal coal centers. Most of them have been systematically conducted for generations, although, in fact, they date back centuries. The exchange simply is the outgrowth of curbstone gatherings. In Newcastle-on-Tyne in the old days, those having coal to sell, those desiring to purchase it, and those possessing the means with which to transport it met on the sidewalk outside the Guildhall. On the days when the weather was inclement the coal men would withdraw into the lobby of the building. The natural outgrowth of the proceeding was the establishment of an organized exchange.

The floor of the exchange is like that in most of our commodity exchanges but without any pit or platform features. Due to the frequent use which must be made of statistical records and other books of reference, a portion of the exchange floor at Newcastle is given up to the library. Telegraph and telephone facilities are maintained on the floor so that members need not leave the spot of actual trading in making use of those necessary adjuncts of the business. The manager of the exchange has an office on the second floor.

The Newcastle exchange is described as "the pivot upon which turns the whole of the coal and the shipping business of the ports on the Northeast coast." While the exchange is primarily devoted to coal, traders in other commodities are eligible for membership. As a result, a vast contract business is conducted there in coal, chemicals and non-ferrous metals.

The present exchange is in the old Guildhall. The building itself was erected before the discovery of America. There have been proposals to house the exchange more pretentiously but sentiment always has been strongly in favor of continuing to trade on the same spot where so much of the coal business of the Northumberland and Durham fields has been conducted for centuries. King Edward III in 1350 granted Newcastle a charter to work coal, but there are many earlier references to Newcastle as a source of coal. The shipment of coal from Newcastle to London was prohibited by a royal decree in 1306, when the King decided the best way to accomplish smoke abatement was to prohibit the use of coal. An old record shows that exports of Newcastle coal were being made to France in 1325.

The exchange is organized as a limited company, the common form of commercial organization. Principal authority for the conduct of the exchange is vested in a floor committee of five members, but, recognizing that the mainspring of the organization is the manager, a high-grade man is employed in that capacity. There are some 1,500 members. A requirement for membership is the purchase of a certain minimum amount of the company's stock.

BRITISH COAL SALESMAN AVOIDS TELEPHONE

At Cardiff the exchange occupies a large central court in a building in which most of the coal interests maintain their offices. It is under the immediate direction of a board of control and is conducted in much the same manner as the exchange at Newcastle. The popular hours are between eleven and one o'clock. During those hours the floor of the exchange is crowded. Few transactions in coal take place anywhere else. For a purchaser of coal to call at the office of the seller or even to inquire by telephone as to prices would be regarded as poor business. On the floor of the exchange buyers engage in what appears to be casual conversation with first one seller and then another. The buyer feels that he is in a more advantageous position to get the lowest price than would be the case were he to call at the office of a seller, thereby revealing the fact that he is anxious to buy.

While the larger operators usually are represented on the floor by a member of their staff, it is apparent that the contacts and the sociability of the daily gathering at the exchange is attractive to everyone, large and small, in the coal business. In addition to being a great stabilizing factor, important benefits flow from these personal contacts between all interests in the district. The problems of the industry are discussed and wider points of view obtained because of these intimate personal contacts. The ingrowing tendencies which come from being isolated day after day at one's own desk are overcome. Incidentally much clerical work is avoided. Most of the business, particularly at

Cardiff, is conducted on verbal understandings. Quite frequently large transactions are consummated without any exchange of written communications.

After seeing these exchanges in actual operation I am convinced that there should be a new effort to establish them in our coal centers. If such an institution were set up at Norfolk—probably the best place to try it out—full advantage should be taken of British experience. Coal men familiar with the territory tributary to Norfolk have expressed the opinion to me since my return that the management of such an exchange probably would have to be vested in a person well acquainted with the local situation.

While it probably would be impracticable to vest the management in an outsider, I do believe that arrangements should be made to bring someone from Newcastle

or Cardiff who is thoroughly familiar with the workings of the exchanges there. He could be engaged as an assistant manager. I have in mind the representative in Cardiff of a large coal interest, whose employers doubtless would be willing to give him a six-month's leave of absence for such duty, since it would familiarize him with American methods and contribute greatly to his value to the concern. He doubtless could be induced to accept, at a relatively low salary, the assistant managership of such an exchange. This would bring to the proposed institution all the facts which have contributed to the success of exchanges in Great Britain, and probably would contribute in no small way to the establishment of a permanent institution in this country which has promise of being particularly helpful to our coal trade.

Dangers Accompany Starting of Electric Mine Fans

Induction Motors Reasonably Safe—Ventilation of Fan or Fan Room with Non-Explosive Atmosphere Recommended Rather Than Permissible Fan Motor

PRESENTED with a question from Denver, Colo., on the dangers of an electrically driven exhaust fan at a mine giving off methane, members of the Coal Mining Institute of America at its meeting of Dec. 20 in Pittsburgh, Pa., proceeded to discuss quite generally the whole question of the dangers of mine fans, exhaust and blower, after standing or when running slowly or normally. Graham Bright, of Howard N. Eavenson and Associates, said sparking was not to be expected where induction motors, particularly of the squirrel-cage type, were used to drive the fan. It was difficult to conceive how motors of that kind could go so far wrong as to spark and ignite gas. Danger certainly existed where direct-current motors were used, because of the sparks on the collector rings.

BIG MOTORS CANNOT WELL BE MADE FLAME-PROOF

True, these could be enclosed, and satisfactory results be obtained with motors up to 20 hp., but he felt it would be difficult to provide in this manner for the safety of motors of 100-hp. capacity or over. Small motors might be so constructed that their use would be permissible in places where gas was occasionally present, but the manufacturers had found that the demand for permissible motors is not brisk, at least not at present. The controller, he added, could be put in an explosion-proof box and so prevented from communicating flame to the outside air.

Asked about the effect of power factor, he said that low power factor in the system would have no adverse effect. Low power factor in the motor itself might cause excessive current with consequent sparking in the controller. However, the controller might be inclosed in a box with a ventilating current feeding the box from some point so distant from the mine that the presence of methane at that point would be unlikely.

W. L. Affelder said that with an exhaust fan of the Sirocco or Capell type the gas could not enter the motor room, because the tendency of the fan was to remove the air from the motor room and the discharge was through a chimney. He later declared that with a disk fan this danger was, of course, to be feared.

J. W. Paul put an entirely different light on the subject by saying that the fan chamber and motor room might be full of gas prior to the starting of the fan and in consequence an explosion might occur even with a blowing fan. He suggested that the electrical parts be put in a casing whether explosion proof or not was immaterial. The casing might be connected with a compressed-air line. Then before starting the fan the air in the casing could be freed of its methanized air by the introduction of a blast of air from the compressor. Unfortunately, some compressed air, owing to the evaporation of lubricating oil, is not wholly free from explosive and combustible qualities.

Mr. Affelder said that when the fan was belt-driven the belt drew air into the motor room from the fan room and so created a risk. Joseph Williams, state mine inspector, of Altoona, Pa., said he preferred a steam-driven fan. With a steam turbine much uncertainty was removed.

Joseph J. Walsh, Secretary of Mines, State of Pennsylvania, said that in the anthracite regions there had been only eight stoppages of steam-driven fans in twenty years and that in a single year there had been an equal number of stoppages of electrically driven fans. Mr. King suggested that the steam-driven fans might not stop but might slow up to such a degree as to make dangerous conditions. Mr. Walsh declared that he had never heard of this happening. Someone said that steam-driven equipment sometimes began to run slow as a result of steam of low pressure being supplied to the prime mover. In that case the power was not thrown off the fan as in the case of the electrically driven equipment, which automatically slows down when the voltage is too low.

He recalled a case where a carpenter who entered the fan house at a gaseous mine in Colorado, after the fan had been stopped 30 minutes, fired the gas in that place with his open light. In the State of Indiana the gas in the fan house during the stoppage of a fan became so abundantly present that it formed a cap on the light of a safety lamp. There was always a danger that the gas would be ignited by the static electricity of the belt if the fan were belt driven.

L. C. Ilsley said that the U. S. Bureau of Mines had at no time recommended permissible motors for use on the surface. A separate motor compartment was preferable to the use of a permissible motor. M. D. Cooper said that before restarting the fan after a shutdown the motor room should be examined with a safety lamp as carefully as a working face.

News Of the Industry

Illinois Must Have Lower Wages or Lose Markets, Honnold Brochure Says

Expert Study Shows Non-Union Fields Have Cut Heavily Into State's Natural Trade — Operators Must Regain Control of Their Mines and Reduce Screenings

Illinois operators are staring at something this week. It is a picture of ruin, or something approaching it. The picture is conjured up in their minds upon reading a powerful document now in circulation from the office of Dr. F. C. Honnold, manager of the Honnold Coal Bureau, Chicago, in which a strong case is set up to prove that the state is fast losing its markets to non-union competing fields and that two things are necessary: (1) That miners' wages in Illinois be reduced, and (2) that a new agreement be made with the United Mine Workers by which control of Illinois coal mines will be regained by the operators from the union.

Graphic charts in Dr. Honnold's pamphlets to operators, miners and others interested in the coal industry of Illinois show that even though the production of Illinois has increased from 6,000,000 tons in 1880 to 60,000,000 tons in 1922, the increase in such competing states as West Virginia and Kentucky has been in far greater proportion, indicating that the non-union regions have been acquiring markets Illinois previously claimed as its own. The relative growth since 1880 of competing states is shown to be as follows: Illinois, 850 per cent; Indiana, 950 per cent; Kentucky 4,150 per cent; and West Virginia, 4,300 per cent. The working conditions of Indiana, bad as they are in comparison with those of non-union states, are shown to be markedly more favorable to the marketing of that state's coal than is true of Illinois.

The loss of Illinois markets during the past seven months is illustrated strikingly in a series of charts showing working time by states and time losses for all causes in Illinois and the five principal competing fields: Western Pennsylvania rail and river mines, northern and central Ohio mines, West Virginia Panhandle district, West Virginia Pocahontas field, and the Harlan County field of eastern Kentucky. In these seven months the "no market" losses were approximately these: Western Pennsylvania, 4 per cent; Ohio, 5 per cent; Panhandle, 7 per cent; Pocahontas, 2 per cent; eastern Kentucky, 4 per cent; Illinois, 45 per cent.

Attention also is directed to the in-

crease in the proportion of screenings produced in Illinois. This increase has been from 19.6 to 48 per cent between 1900, three years after the basis of paying miners changed from lump to mine-run, and 1923. Doctor Honnold estimates that this increase has caused a loss of between \$10,000,000 and \$12,000,000 a year to Illinois operators.

This is pointed out as "a condition wholly without justification but impossible of correction unless and until co-operation of the workmen is obtained. This co-operation is necessary both from the individual workman and from the union organization of the United

Mine Workers. It is a result of carelessness and indifference instead of the application of skill and interested co-operation" in spite of that clause of the agreement written in 1897 and continued to this day in which the union guarantees "heartly support and co-operation in disciplining any miner who, from ignorance or carelessness, or other cause, fails to properly mine, shoot and load his coal."

The screenings produced in Illinois through 2-in. round perforations (comparable to the 1½-in. openings in the bar screens used at the time the shift from lump to mine-run basis was made in 1897) have not "since April 1 of this year returned beyond 60 per cent of production cost." The average loss in only twenty Illinois mines has been 76.9c. per ton, or a total of over \$2,000,000. The average loss for 43 months from April 1, 1919, to Oct. 30, 1923, at the same twenty mines was 50c. per ton.

Such statistics as these, backed up by certain statements which Dr. Honnold makes in the pamphlets, are waking many Illinois operators to a clear realization of a situation which they have only dimly realized before. Most of them have had fragmentary knowledge of what confronted them as men in the business of producing coal, but this has served to crystallize their knowledge.

TIME WORKED AND LOST BY FIELDS

Diagram showing per cent of full time worked and time lost by causes, averaged for the seven months, April to October, 1923. The fields shown, one for each vertical column, are: (1) Western Pennsylvania rail and river mines; (2) Northern and central Ohio mines; (3) West Virginia—Panhandle district; (4) West Virginia—Pocahontas district; (5) Eastern Kentucky—Harlan County field; (6) Illinois.

Transportation Parley Called for Jan. 9

A national conference on transportation, to be held in Washington, Jan. 9, 10 and 11, has been called by Julius H. Barnes, president of the Chamber of Commerce of the United States. Two hundred leaders of recognized standing in commercial, educational, financial and industrial fields have been invited to take part in its deliberations and in the discussion of problems involved in the development of an adequate national transportation system. It is expected that every state will be represented at the conference.

"The expanding transportation needs of America can be easily visualized," said Mr. Barnes, "and must be resolved so that national wealth and individual production may be marketed into consumption. All production, agricultural and industrial, is dependent on adequate and ready distribution."

Coal-Mine Accidents Took
167 Lives in November

Fatal accidents at coal mines throughout the United States during November numbered 167 as compared with 153 in the previous month and 370 in November last year, according to a report by the U. S. Bureau of Mines. The fatality rate for the month was 3.29 per million tons, based on 50,783,000 tons of coal produced, as compared with 2.64 in the preceding month and 6.88 in November a year ago.

The year 1923 to the end of November shows a total of 2,254 coal-mine fatalities and an output of 593,000,000 tons of coal, the fatal-accident rate being 3.80 per million tons. The corresponding period in 1922 showed 1,813 men killed, 410,000,000 tons of coal produced, and a fatality rate of 4.42. Although in 1922 the five-months' strike reduced the number of men working in the mines, and thus also reduced the number of men killed, the cost of coal during the past eleven months of 1923, ton for ton, in number of lives lost, has been 14 per cent lower than in 1922.

The reduced fatality rates for 1923 are evident in all of the principal classes of mine accidents. For example, falls of roof and coal, which usually account for nearly half of all fatalities at coal mines, showed a decline in the death rate from 2.01 per million tons in 1922 to 1.78 per million tons in 1923; haulage accidents, normally comprising about 18 per cent of all deaths at coal mines, showed a de-

cline in the rate from 0.73 to 0.64; the rate for gas and dust explosions fell from 0.75 to 0.61 in spite of three bad explosions during the past eleven months. The fatality rate for all classes of accidents to men working underground was 3.49 per million tons in 1923 and 4.03 in 1922.

Reorganization of Federal
Departments Deferred

The proposal that the administration show its faith in the reorganization of the federal departments which it is advocating, by carrying into effect a part of the program by executive order, has met with delay. It is understood that administration leaders feel that the plan should be discussed with the joint congressional committee before any such action is taken. It has been impossible to obtain a meeting of the committee for that purpose. It is known that friction exists between members of the committee and their chairman. Whether or not this friction is such as to prevent an ultimate meeting of the committee has not been determined as yet. At any rate, it is believed that no transfer of bureaus will be made by executive order until further efforts have been made to discuss the matter with the congressional committee on reorganization.

Proposals to create a Department of Mines have failed to enlist the support of President Coolidge, according to a report from the White House. The President, it is said, does not look with

Dr. R. R. Sayers
Chief Surgeon, U. S. Bureau of Mines

favor upon the addition of another department to the government, but does feel that the present Bureau of Mines could be effectively strengthened and enlarged.

Incidentally the President took occasion to set at rest a persistent rumor that the Bureau of Mines was to be transferred by executive order from the Interior Department to the Commerce Department. The President, it was stated officially, has no thought of issuing such an executive order.

Coal-Mine Fatalities During November, 1923, by Causes and States

"Let Well Enough Alone" Probable Policy of Union and Operator Leaders

Disaster Seen in Wage-Negotiation Course Favored by Radicals of Either Side—Usual Period of Uncertainty Likely to Precede Agreement—Legislative Bugaboo May Figure

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Leaders of the United Mine Workers and among the coal operators alike are thought to be convinced that of all times next spring would be the worst possible time to have a bituminous-coal strike. There is every reason why, for their own welfare, these interests should let well enough alone and continue operation on the same basis during the next coal year as during this coal year. Nevertheless there are operators who are willing to go to the mat with the union in an effort to reduce wages. There is even a larger element in the United Mine Workers who would be willing to insist upon a six-hour day, a five-day week and a 20-per cent increase in wages.

To the operators who have a grasp of the general situation it must be entirely apparent that there is not a ghost of a chance to reduce the wage scale next April. To the equally intelligent leaders of the United Mine Workers it must be obvious that the application of the thirty-hour week and an increase in wage would simply lay their organization open to more disastrous non-union inroads than already have taken place. The union has lost its hold completely in the New River field. Its influence is all but gone in Kanawha. Throughout the whole northern half of West Virginia its strength is only one-half of that a year ago. For the union to insist upon extreme demands would be to invite ruin.

These facts are so well understood among the operators and among the mine workers who will participate in the wage conference that the logical thing for them to do would seem to be to agree promptly to extend the present agreement for another year. It is widely believed that this will be done eventually. It is doubtful if any such direct and businesslike result will be attained. A show of great determination to reduce wages must be made to appease the minority of operators who want to attempt the impossible. A sop must be thrown to the radical element in the ranks of the mine workers, so there will be a great display of demands known to be unobtainable. As a result, the usual three-months' period of uncertainty and dissension—in some ways nearly as bad as a strike—probably will precede this new agreement.

There is another reason for believing that neither side is going to precipitate a strike this year; Congress is in session. It is going to take all of the legislative influence of the operators and all of that of the union to prevent legislation, which neither wants, at

this session. Let there be a strike and the demand for this legislation will be such as to insure its prompt enactment.

There is one great temptation dangling before John L. Lewis. He knows that the federal government has formed a habit of interfering promptly when a strike is actually called. In such a situation he is at a great advantage. His capabilities are suited particularly to the masterful handling of such a pass. This was demonstrated anew during the recent anthracite strike, when labor entered the wage-scale conference with no hope of doing more than maintaining the *statu quo*.

If a strike is avoided, the chances seem to favor the passing of the session without coal legislation. The administration has shown no disposition to urge even the legislation recommended by the Coal Commission. Secretary Hoover is outspoken in his belief that the main remedy needed by the coal industry lies outside the legislative field. The operators oppose it. Labor opposes it. On the eve of a presidential campaign, Congress is more disposed to discuss such major issues as railroads, taxation, soldier bonus and immigration. These subjects have vote-getting potentialities far in excess of any coal legislation at a time when bituminous coal is not yielding pre-war prices and much of it is being marketed at an actual loss.

Big Snowbirding Deal Is Made in Illinois

For the first time, a large volume of Franklin County (Illinois) coal has fallen into the hands of an agency which will sell it direct to consumers by mail and otherwise. A contract is now in process of completion under which Simon Levy, a man who has grown in the coal business of the middle West until he now operates several direct-by-mail and direct-to-consumer companies, headed by the Boylston Coal Co. of Chicago, will receive the entire output of the two Franklin County mines of the Southern Gem Coal Corp. of Chicago. To gain control of this coal, Mr. Levy's interests have underwritten a Peabody Houghteling bond issue on the two properties—an obligation which has been embarrassing the Southern Gem corporation.

The details of the new contract between the Southern Gem and Mr. Levy remained to be cleared up at the end of last week. In one quarter it was expected that the contract would cover the output of the mines for five years. Mr.

Down Near Herrin

They've had a pleasant year in "bloody Williamson" County, Illinois, wherein lies Herrin, the town famous for the mine massacre of 1922. The coroner's annual report for 1923 shows sixteen murders, twenty deaths in mine accidents, ten suicides, eight deaths from undetermined causes and two from alcoholic poisoning. Just before Christmas a "dry" squad raided a list of drinking places, engaging in a gun battle in which a liquor defender was one of the principal defendants in the Herrin trial a year ago. Altogether an enjoyable time was had by all present.

Levy wanted ten. A certain running time and a certain price per ton were to be guaranteed the operators, but these were not announced. Mr. Levy said that his own selling organization would handle the domestic sizes, and that an arrangement would be made with the operators' selling department to market the steam sizes. It is probable the output of the two mines will total 1,500,000 tons a year.

This arrangement is expected to cause various changes of personnel in the Southern Gem Coal Corporation, but none of the other mining properties of the company is involved.

Must Commerce Department Abandon Statistics?

In view of the decree issued in connection with the cement manufacturers' case, the Department of Commerce has referred to the Department of Justice the question as to the propriety of collecting statistics such as are gathered by that department. While the decree in the tile manufacturers' case indicated that returns to a government agency are allowable, it is apparent that the effect of the department's figures is the same in many particulars as those handled by trade associations. The Department of Justice is understood to hold the position that it is contrary to the law for a trade association to submit figures to trade publications. In fact it is turning its attention at this time to associations which distribute their figures only in that manner.

Jan. 1 Coal Stock Report

A report to cover all coal stocks, as of Jan. 1, is to be issued by the U. S. Geological Survey. The Department of Commerce is co-operating in the gathering and compilation of the material, which will require all of the month of January. A report will be made available as soon after Feb. 1 as possible.

"The First Robin" Seen as Forerunner Of Forthcoming Soft-Coal Wage Parley

The following is reprinted from a recent bulletin of the Central Pennsylvania Coal Producers' Association:

"The prospect of coal legislation at the present session of Congress and the situation in the bituminous mines where part time operation is now the rule were discussed with President Coolidge today by John L. Lewis, president; Philip Murray, vice-president; Ellis Searles, editor of the *Journal*, of the United Mine Workers of America, and by Secretary of Labor Davis,' states this morning's paper.

"The article says that the gentlemen representing labor declined to say what was discussed with the President and they had merely called to 'pay their respects.' The report says, however, 'the President's message to Congress concerning legislation and the matter of negotiations this winter between the bituminous operators and miners for renewal of the wage contract in the coal mines, which expires April 1 next,' were the topics talked about in this conference, with particular attention paid to that part of the President's message favoring the immediate establishment of a commission by the President, 'empowered to deal with whatever emergency situation might arise, to aid conciliation and voluntary arbitration, to adjust any existing or threatened controversy between employer and employee, when collective bargaining fails, and by controlling distribution to prevent profiteering.'

"Previous to this time the discussion of wage agreements in the union fields began with the joint conference of miners and operators representing the union districts.

"Discussions now begin by dire predictions of strike in the union fields, emanating usually from non-union operators in other states. One could not suspect in such cases that 'the wish might be the father to the thought.' This unselfish devotion of non-union coal operators to the country's good during strikes in the union fields is most inspiring. That such condition enhances the value of their coal greatly, and therefore their profits, of course has nothing to do with their concern about the possibilities of a strike in the union districts.

"As 'the first robin is a sign of spring,' so we must take these signs as forerunners of an interest in our forthcoming negotiations, stronger than mere curiosity.

"Irregular operation of mines arises from a great many conditions, all of which have been discussed at great length by coal operators and coal miners, as well as experts and near-experts of every variety during the past five years. The one great cause of irregular operation in the union fields is the ability of the non-union fields to produce coal at a lower cost than the

union mines. Their business is more profitable and moreover is always profitable, made so at the expense of the wage schedules. This fact has tended to increase the development of the non-union fields more rapidly than the country required. It will continue to cause overdevelopment in the non-union fields so long as the union is able to maintain a wage schedule so much higher than the non-union wage schedules as to insure non-union mines a profit.

"So far as we know, the union coal operators have not been consulted as to their necessities following the termination of the present wage agreement April 1 next. Neither do we think it important that they be consulted.

"It is important, however, that the United Mine Workers of America should understand that unless they are able to establish conditions in the union fields of this country where the coal operators and the coal miners in such fields can compete for the business of the country upon a fair basis with the coal operators and coal miners of the non-union fields, any continuation of the present basis means ruin to many union coal operators and continued idleness to thousands of union coal miners during the coming year.

"If the policy of the government as indicated by various statements and decisions and reports of different governmental bodies is to eliminate the uneconomic coal mines of America by establishing car rules, etc., so as to accentuate the natural law of competition, the union may as well understand that the present policy of wage-scale making and enforcement means that all of the union mines in the fields where keen competition now obtains as against non-union mines may be listed as uneconomic. Operating conditions in the union fields are just as good, just as efficient, the quality of their coal is just as high (and, if we believe the Union, labor more skilled) as compared with the non-union fields. As between mines where natural conditions are equal, union mines will be wiped out as a result of unfair competition and not the mines that are naturally uneconomic. The union miners must come to understand this: if they are going to have work and their union is going to continue to be a strong force in their lives, they must bear their share of the burden of contest during the struggle 'for the survival of the fittest.'

"Non-union operators competitive with and contiguous to central Pennsylvania have already cut wages 25 to 35 per cent. The reduction, as made, affects a large volume of tonnage, probably five to six million tons per annum. More reductions, in our opinion, will follow in the non-union fields, the day when union coal operators have been safely signed, sealed and delivered by another agreement."

Harrison D. Mason

Recently re-elected secretary-treasurer Coal Mining Institute of America.

Taylor Coal Co. Takes Over Bickett Mines

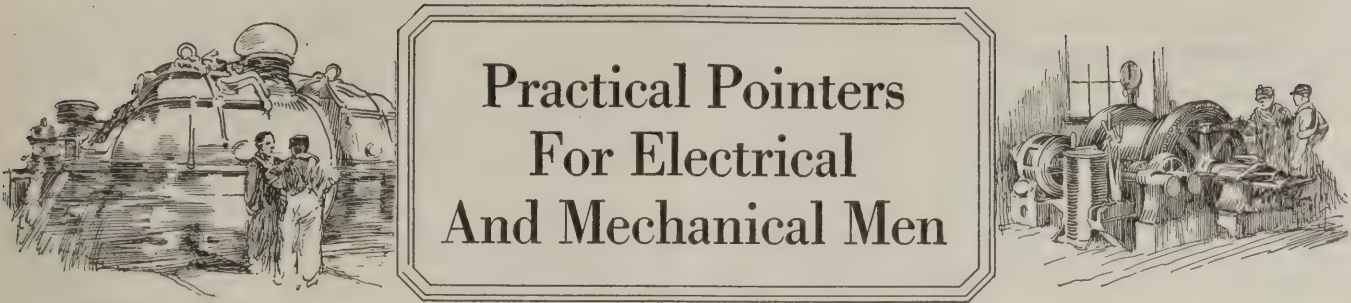

The Taylor Coal Co., of Chicago, has acquired the Bickett Coal & Coke Co., effective Jan. 1. By the merger the Taylor company takes over the properties of the Franklin Coal & Coke Co., at Royalton, Ill., and the Chicago & Sandoval Coal Co., at Centralia, Ill., which will practically double the output of the Taylor company to 15,000 tons per day.

Three mines are involved in the transaction, two at Royalton and one in Christian County. The Royalton mines have a daily capacity of approximately 5,000 tons. Extensive improvements are planned at Royalton, Mr. Keeler, manager of sales of the Taylor company, announced.

C. A. Bickett, former president of the Bickett Coal & Coke Co., will become a director of the Taylor Coal Co., and Ray Jones, sales manager of the Bickett concern, also will join the sales organization.

A Two-Foot Hole

A hole barely 24 in. in diameter was the aperture through which death came to the three men killed in the recent flooding of the Radium mine of the Aluminum Ore Co. of America near St. Louis, Mo. A drill broke through into an old water-filled working whose proximity was unguessed and a sufficient flood of water and gas came through to drown the mine. Two pumps are now throwing 8-in. streams out of that mine and must continue for an estimated sixty days before mining can be resumed. Nearly 200 men are thrown out of work for that length of time. The cost to the company is great. All because of careless mapping—and a 2-ft. hole.

Practical Pointers For Electrical And Mechanical Men

How Underground Substations Should Be Ventilated to Obtain Full Rating

In the modernly equipped non-gaseous mines of the present day, purchased power seems to have proved the most economical and efficient, due to the fact that the required operating voltage may be maintained at the working face of the coal and also the usual power-house expense and troubles eliminated; hence the underground substation is rapidly taking its place in the industry.

Although these substations are originally installed at or near the working face, before long the mine has developed a considerable distance from the point where the substation was located, and as most of these isolated stations are equipped with automatic reclosing circuit breakers for the control of the direct-current side, an operator is not required. Therefore the substations are practically forgotten until development of the mine has advanced to such a point that the voltage drop is again realized, and the substations must be moved nearer the workings. Long before this condition arises it is probable that the paths of ventilation will be changed, the fans moved closer to the workings, etc.; therefore the path for ventilation that was originally provided for the substation will be badly crippled or blocked entirely. As a result the motor-generator set or converter—whichever may be employed for converting the alternating current into direct current—must pay the first penalty, the second being paid by the

FIG. 1—VENTILATION BEFORE FAN WAS INSTALLED

The same air was continually circulating through the converter and thus causing a gradual increase in temperature until it became a detriment to the insulation, commutator and brushes, also cutting down the capacity and efficiency of the machine.

maintenance man in charge of the equipment, and the third by the operators of the mine.

While nearly all manufacturers of electrical machinery design their apparatus to generate its own ventilation, this provision is far from ample when no supply of fresh air is available; in fact it is of no practical help, as it only circulates the same volume of air through the machine again and again. Therefore a means must be provided to circulate a much greater volume of air.

Referring to a condition that I believe will serve as an average experienced along such lines: The room temperature at 7 a.m. was found to be 60 deg. F., as the machine had been standing idle since 4:30 p.m. of the day before. This machine was a Westinghouse synchronous converter having a capacity of 150 kw., 275 d.c. volts and an allowable temperature rise of 55 deg. C., and an additional 5 deg. rise, at the commutator and rings, as well as an allowance for 100 per cent momentary overloads without damage or excessive temperature rise, but at no time did the machine accommodate a peak load of more than 51 per cent while the temperature conditions were under test.

At 7:15 a.m. the converter was started and thrown on the line, and the results of tests taken throughout the day are as follows:

Time	Room Temp.	Field Surface Temp.
9:15 A.M.	74 deg. F.	81.3 deg. F.
10:15 A.M.	82 deg. F.	89 deg. F.
12:15 P.M.	96.5 deg. F.	116 deg. F.
3:15 P.M.	109 deg. F.	163 deg. F.
4:20 P.M.	110.5 deg. F.	176 deg. F.

Thus the armature and field insulations were being rapidly destroyed, commutator burned, brushes damaged and the general efficiency of the machine greatly lowered.

By experiment it was learned that the air in this station must be replaced one and one-half times each and every minute to relieve this condition in a satisfactory manner. The dimensions of the room were 11 ft. x 17 ft. x 10 ft. 6 in.; hence, approximately 1,963.5 cu.ft. of air was contained in the room, which would require a fan capable of removing $1,963.5 \times 1.5 = 2,945$ cu.ft. of air per minute. The nearest to the requirements just determined was a Venturi exhaust fan, listed by the Westinghouse Electric & Manufacturing Co., of East Pittsburgh, Pa. The capacity of the fan

selected was 3,250 cu.ft. per minute, this being nearest to the requirements.

The fan just mentioned is direct connected to a direct-current motor of the series-wound type with a speed of 900 r.p.m. having a full load current of 0.11 amp. at 275 d.c. volts. This fan was connected through suitable fuses to the direct-current terminals of the converter; therefore it does not remain idle during the moments that the d.c. circuit breaker may be open, nor is it subjected to the full-line voltage while starting, as the fan attains its maximum speed as the voltage of the converter builds up to its maximum, considering that most all small converter units are started from the alternating-current side of the machine.

The maximum temperatures after the fan was placed in operation are as follows: At 4:20 p.m., room temperature, 64 deg. F.; fields, 98 deg. F.

FIG. 2—PROPERLY VENTILATED SUB-STATION AND CONVERTER

After the fan was installed the air in the substation was changed every minute and a half. The circulation of air through the converter allowed the machine to be operated to its full capacity without any damage or danger of overheating.

Prior to the time this fan was put in service, the average life of a grade No. 619 National Carbon Co. brush for the d.c. side of the converter was 46 days, but since the fan was put in service the same grade of brush shows only 9/32 in. of wear after seven and one half months of service.

From this data it may readily be proved that in only a short period of time the brush savings alone will pay the cost of the ventilating fan plus the labor required to install it.

The accompanying illustrations show the natural ventilation before the fan was installed and the air currents after the fan was installed.

Electrical and Chemical Engineer.
Piney Fork, Ohio.

Combustion Control and Best Boiler Practice

Will you please give me solutions to the following questions:

(1) In a certain plant coal having a heat value of 14,000 B.t.u. per lb. is used. If the flue-gas temperature was 450 deg. above the air in boiler room, and 25 lb. of air was supplied per pound of coal, what percentage is lost in stack gases? The specific heat of chimney gases is 0.24.

(2) What gas in large proportions in chimney gases indicates insufficient air being supplied to the fuel?

(3) What gas in the chimney indicates that too much air is being supplied to the fuel? What proportion of this gas is good practice?

(4) What instrument is commonly used to test flue gases?

(5) How is the condition of the boiler indicated by a change in temperature of the chimney gases, and why?

Chicago.

C. E. PETERSON.

(1) The precise answer depends upon the analysis of the coal, for if 25 lb. of air per pound of coal is supplied, the weight of flue gases per pound of coal will be this amount of air plus the carbon or other elements which are added to it. If the coal were 100 per cent carbon, the amount of flue gas per pound of coal would be 26 pounds and the heat lost under the conditions named would be 20 per cent. This condition, of course, never exists in actual practice, as there always is a certain percentage of ash and hydrogen. The latter element burns to water and is not shown in the analysis of flue gas for which the samples are collected over water.

(2) CO, when present in any amount always indicates insufficient air. High percentages of CO₂ also are likely to be accompanied by a certain percentage of CO.

(3) Oxygen, of course, indicates air which has not been used in combustion. It is always necessary to supply air in excess of that theoretically required. In present-day practice 6 to 8 per cent. of oxygen, depending upon whether the boilers are hand or stoker fired, would indicate good practice.

(4) The instrument commonly used is what is known as the Orsat machine. This apparatus consists of a burette graduated up 100 c.c. and surrounded by a water jacket. This burette is connected to a manifold, which in turn is connected to three or four pipettes containing various reagents for the absorption of different elements in the gas. These pipettes are in turn connected to rubber bags which permit the gas permanently in the rear half of the pipette to pass out of the pipette to permit the introduction of the gas to be analyzed into the front bulb of the pipette. Each one of these pipettes is provided with a stop cock to shut it off from the manifold. The burette also is provided with an opening to which is connected a three-way cock,

one opening in this cock connecting to the tube through which samples are drawn and the other for discharging analyzed samples to the atmosphere. At the bottom of the burette is placed a connection for a rubber tube to the end of which is connected an open bottle.

The method of using an Orsat is to fill the burette with water, open the three-way cock to the sampling tube and draw a sample of gas into the burette by permitting the water therein to flow into the bottle connected to the bottom of the burette. Exactly 100 c.c. is drawn off after two or three samples have been drawn and rejected so as to be sure to get the proper sample from the boiler. The sample is then passed into the first pipette, which contains a solution of caustic potash for the absorption of carbon dioxide, by raising the water bottle, which causes the water to flow into the burette and displace the gas sample. After being permitted to remain in the pipette a sufficient length of time, the gas is returned to the burette by lowering the water bottle, and the amount of gas remaining is determined. The difference between this amount and the original 100 c.c. represents the carbon dioxide absorbed in the first pipette.

The second pipette contains an alkaline solution of pyrogallol for the absorption of oxygen and the remaining pipette or pipettes contain an acid solution of cuprous chloride for absorbing the carbon monoxide. The process of absorbing and measuring the oxygen and the carbon monoxide is the same as that described for absorbing and measuring the carbon dioxide. After the three reactions have been performed, there will be considerable volume remaining, which is nitrogen.

(5) Increasing temperatures of the chimney gases indicate that the boilers are dirty, either internally or externally. Scale or soot existing on boiler tubes decreases the flow of heat through the boiler tubes and therefore makes the boiler less efficient and the temperature of the chimney gases high.

Information on Heating of Electrical Conductors

Answering the recent inquiry on heating of conductors in your paper, we feel we cannot do better than give you below the report of our research engineer on the subject of heating of conductors in conduits:

"We have no data here giving methods for computing the proper current-carrying capacity of single conductor cables for 3-phase a.c. when in iron or steel conduit. The problem is not possible of purely mathematical solution. The chief difficulty is the calculation of the induced current in the conduit due to the current in the copper conductor.

"The information desired can be obtained only by a long experimental investigation. About the only thing one can do is to calculate the current along the lines suggested and then use

a factor which will give a fair degree of agreement with actual practice. This factor will be less than one, and is obtained by dividing what is considered the proper current by the computed current.

"With reference to the specific problem cited, if the 1/0 A.W.G. conductor was alone in the conduit, it might just meet the limit in temperature. Also, this will be influenced by how close the other conductors will be."

THE OKONITE CO.

Installing Cables in Shaft

With the more general use of alternating current for power transmission in the mines and the use of voltages greater than 440, much more consideration must be given to the shaft cable.

These cables should rarely be installed in the main hoisting shaft because of the difficulty of installation, maintenance and likelihood of accident. Whenever possible, the cable should preferably be placed in a separate borehole. A serious objection to the cable being placed in the shaft is the liability to damage from being cut by pieces of coal or damage caused by accidents with the hoisting cage in the shaft.

When cables are installed in a shaft, joints are among the most important items to be given attention. A good joint should be mechanically strong and water-tight. Joints should never be made directly in the shaft unless absolutely necessary, because of the danger in working upon them and the greater liability to breakdown.

A better arrangement is to have the cable continuous from the top of the shaft to the bottom or ordered in sections of such length that the joints may be made at the different shaft levels or veins. Whenever the joint must come in the shaft it is advisable that it be made in an inset in the shaft for the purpose; then the workmen will be in a better position to do a good job and still not be in any great danger.

Joints should be made only after the two cable ends have been securely anchored, the anchorage being designed in accordance with the type of joint. If the joint is of sufficient strength to take the weight of the cable the anchorages may be removed when the joint is completed, but usually some form of support must be maintained for the cable.

One lb. carbon oxidized with perfect efficiency equals:

11,325,000	ft.-lb.
14,600	heat units.
1.11	lb. anthracite coal oxidized.
2.5	lb. dry wood oxidized.
22	cu.ft. illuminating gas.
4.275	kw.-hr.
5.733	hp.-hr.
15.05	lb. of water evaporated from and at 212 deg. F.

Problems In Underground Management

Dynamite Unquestionably Exerts Its Force Equally in All Directions

Tests Show Guncotton Exploded Makes Holes of Same Size Whether
Placed Below or Above Plates of Steel—With Lead
Blocks Pressures Proved to Be Equal

By J. E. CRAWSHAW

Explosives Engineer, U. S. Bureau of Mines, Pittsburgh, Pa.

"Dynamite acts down and black blasting powder acts up," is a statement frequently heard around the mines and from men whose practical observations may seem to warrant their making the statement. Nevertheless those who have studied and tested explosives are convinced that it is an erroneous opinion, arising from a failure to consider all contributing factors.

Tests showing that the force is equal in all directions are simple and easily made, and many explosives investigators have performed them. Before presenting these tests it might be well to consider one or two cases of the use of such explosives which often lead the unwary falsely to conclude that dynamite does not exert an equal disruptive force in every direction:

TWO MISLEADING INDICATIONS

(1) The use of dynamite in the form of an "adobe" or "mud-capped" shot where a mass of explosive detonated on a rock shatters it into many pieces, the broken rock which before the explosion was below the dynamite being the only visible result of the explosive force released. In discussing this action no consideration usually is given by mining men to the force expended on the surrounding air.

(2) The action of dynamite in "brushing" the roof of a coal bed, the explosion throwing out shattered pieces of rock, leaving a crater in the immediate vicinity of the charge. An explosion of black blasting powder will, on the other hand, break the rock upward and outward from the charge, bringing down a large mass of the rock. The difference in the result is not due to the fact that the one shoots up and the other shoots down but that the gases from the one are more rapidly developed than those from the other and so have time to penetrate the cracks and fissures before the rock has given way along the lines of least resistance.

Dr. Charles E. Munroe conducted a test in which he placed disks of guncotton against plates of iron and steel. The holes made by the explosion of the guncotton were of the same size regardless of whether the disk of guncotton was placed above or below the metal plate. This is convincing proof that high explosives exert their power equally in all directions.

At a later date Dr. Walter O. Snelling extended the method of Dr. Munroe; but instead of measuring the forces by the size of the holes in iron plates, he

used the compression produced in small lead blocks. In each trial the explosive and lead block were held rigidly in position. In the first two tests with each kind of explosive the charge was placed above the lead block, while in the other two tests the charge was placed below the lead block, so that the downward and upward pressures were measured, respectively. A measurement of the four blocks used showed equal compression in each instance.

In the practical use of explosives, however, this force which is applied equally in all directions acts against unequal resistances and the effect obtained in any one direction can be equal only to the resultant of the resistances which act in the opposite direction. As soon as the confined gas is released, the force no longer acts. It is evident therefore that when the explosive is not exposed on all sides to an equal resistance the results of blasting may be such as to cause a ready misinterpretation of the real action of the explosive.

Apportioning Working Places To Miners by Lot

By ALFRED JONES
Wheeling, W. Va.

Places in the coal mines are often of extremely unequal desirability and that fact permits, and in truth invites, the rankest kind of favoritism on the part of the foreman who distributes them. Even where the foreman means to treat all fairly he is faced by the fact that he has no clear basis on which to decide who is entitled to the better places and so frequently he yields to the loudest clamor, to some personal preference in regard to the claimant or perhaps to the solicitation of someone related to him or a near neighbor.

In the Durham mines of the north of England the working places are distributed by lot. The system is known as cavilling. That this plan is popular is evidenced by its long continuance. Every man feels he has an equal chance and almost all of them accept their lot and are satisfied to plod along in the place afforded till the next drawing. Of course, if a man does not like his place he can leave the mine but this he rarely does.

With this arrangement the charge can no longer be made that the mine foreman is paid for the better places. To accuse a boss of taking money for

that purpose generally results in the miner being fired on the spot. Nevertheless men do pay \$50, even \$100, for a good place. Foreigners just arrived, not considering the giving of money for this purpose to be wrong, are quite willing to pay that much cash for an advantage which will enable them in a short time to recoup themselves for the expenditure.

Not only are men sometimes favored who pay the boss money but men are removed for not paying it. To excuse his action a foreman will give some reason having little foundation in fact. He will declare that the place "is going too slow" or that the man "is loading dirty coal" or he may curtail the miner's turn of cars. A favorite scheme, however, is to give the man a partner he doesn't like hoping he will quit rather than work with him.

In the system allowing men to choose their places by lot two men may ask the foreman to permit them to exchange places because, for various reasons, some men like places that others dislike. The change is then beneficial to both. The only disadvantage of the English custom is the loss of time when the men change their working places. However, that rarely exceeds a half a day and no manager will begrudge that time if the men by reason of the arrangement are made content.

Reply to question on this subject delivered at Dec. 19 meeting, Coal Mining Institute of America.

Discussion

Some, at Least, Were Quizzed In Presence of Gas

With indignation I read a letter written by a superintendent in the Dec. 6 issue of *Coal Age*, page 863, in which he criticized the work of the Board of Examiners at the last examination of mine foremen and firebosses and questioned the validity of the certificates issued by them. He no doubt refers to the examinations held this summer at two of our mine schools.

I happen to know much about the routine and character of the work performed at State College this summer, where a class of about fifty men were preparing themselves for certificates, and I must say that, judging from the way these men worked and the completeness of their instruction, I do not see how anyone can question their qualifications and ability to perform the duties of any appointment within the range of their certificates.

The mining law was taught and discussed most thoroughly and frequent oral tests showed that the students had a good conception of what the law means to the mining man. "Superintendent" says that candidates for fireboss certificates were not submitted to an oral examination. Those who believe that are certainly laboring under a false impression. I will admit they were not examined inside a mine, but the law reads that candidates for certificates "shall also have undergone all oral examination in the presence of explosive gas," which examination they did take in a chamber containing gas of that character.

By a regular course of lectures, demonstrations and tests the men were taught the construction, advantages and disadvantages of the principal types of approved flame safety lamps. They also were given demonstrations of the action of these lamps in a gaseous mixture. Let me add that at considerable expense and loss of valuable time these men took advantage of these courses, and they should be given credit for their enterprise.

M. S. L.

Joseph J. Walsh, Secretary of Mines, State of Pennsylvania, in a letter dated Nov. 23 to James T. Beard, says: "The examining boards under the new act, as under the old act, have authority to make rules for the conduct of the examinations. The new act, though it omitted the clause regarding the oral examination in the presence of explosive gas, gives the boards authority to make the examinations as thorough as they desire."

This disposes of the question as to whether examinations omitting the oral examination of the applicant in the presence of explosive gas are valid or

invalid. They are distinctly valid, but the question whether they fill the need is still to be answered. In truth, the examination of firebosses is both a mental and a physical test. The fireboss may be clever, responsible and well instructed enough for the job but if he cannot see a cap on a lamp, cannot distinguish it when caused by small percentages of gas, then he is not a fit man though he had all the knowledge in a mining pocketbook or all the wisdom of the oldest fireboss in the industry or had a medal for long and faithful service. When will it be learned that no college or school can endow a man with powers of color perception or grow an arm on the stump of a one-armed man?—EDITOR.

Will Classroom Examination Fill the Bill?

No one can effectually examine the qualifications of a fireboss anywhere but in a mine, and for this reason I believe that the reader signing himself Superintendent in *Coal Age* of Dec. 6 performed a public service in calling attention to the importance of hewing close to the line laid down in the Bituminous Mining Law of Pennsylvania.

After many conferences and prolonged discussion with mining engineers and mine officials, the mine inspectors of the bituminous region of Pennsylvania, under the leadership of the late James R. Roderick, then chief of the Department of Mines, at Harrisburg, submitted to a committee of the State Legislature a complete and comprehensive draft of what they considered would make a thorough revision of the mining laws then on the statute book.

This entire revision was promptly enacted by the Legislature sitting at that time and approved by the Governor of Pennsylvania, June 9, 1911. The revised law has generally been conceded to be a model and many of its features have been incorporated in the mining laws of several of the states. Notwithstanding, there have since been made a number of revisions of different sections, as suggested by the changing conditions and requirements in the mines.

Until the present year, May 31, 1923, applicants for fireboss certificates were supposed to be given an opportunity to demonstrate their ability to detect a flame cap in a safety lamp exposed to an explosive mixture of gas and air. It may be assumed that some of the examining boards misinterpreted the meaning of the expression "oral examination in the presence of explosive gas."

Though some of the boards took their applicants for fireboss certificates into the mines and subjected them to the

practical test, other boards may have employed means of making this test by exposing a safety lamp to an explosive mixture of gas and air in a chamber or box, on the surface, the apparatus being provided with a window through which the action of the lamp flame could be observed by the candidate. Still other boards may have satisfied themselves of the ability of the candidates to perform the duties of fireboss in gaseous mines without putting them to the practical test.

This difficulty appears to be the only reasonable excuse for the dropping of this clause when Art. 24 was revised in its entirety by the last legislature, and approved by Governor Pinchot, May 31, 1923.

There are many firebosses now employed in making the test for gas in bituminous mines who fail to detect the presence of gas until the mixture has reached 2½ or even 3 per cent. This is largely due to failing eyesight, and in some instances color blindness may be the cause. The danger of this condition is easily recognized when it is remembered that 1 per cent of gas or less is extremely dangerous in the mining of a soft inflammable coal.

How Ohio Lost an Output Of Six Million Tons

Diversion of business by the government and shipment of inferior grades of coal into Ohio from the "crescent" has cost the southern Ohio operators the loss of much of their Ohio business is the conclusion of W. D. McKinney, secretary of the Southern Ohio Coal Exchange.

Mr. McKinney points out that the demoralization of the district is due primarily to the federal government's war orders compelling Ohio producers to ship their entire output to the Northwest. The loss this year is more than 6,000,000 tons in production.

"The severely cold winter of 1917-18 found the country short of fuel, particularly the Northwest, and the U. S. Fuel Administration directed that all the domestic coal of southern Ohio be directed to that section," Mr. McKinney said. "Practically every pound of screened lump produced in this field was taken away from the operator's trade in Ohio, Indiana and Michigan and sent to the lakes, where it was transhipped to the Northwest.

"This opened the Ohio retail field to the Crescent district, south of the Ohio. There are few laws that govern grading of coal in this district, with the result that people of Ohio burned inferior and dirty coal, in the majority of instances, not knowing its source. Consequently coal from the southern Ohio district was given, figuratively speaking, a 'black eye.'"

Mr. McKinney said further that coal from the Hocking, Pomeroy, Crooksville and Jackson districts of southern Ohio is equal for general domestic and steam purposes to coals of the same rank produced in West Virginia.

Production And the Market

Weekly Review

The anticipated slump in the anthracite market arrived on scheduled time. Demand for all sizes fell off and independent coals was quoted last week, in many instances, as low as at any time in 1923. Although there was a heavy cut in production due to the holiday season, there was sufficient coal on hand to meet all needs. Movement of premium coal is more difficult and producers and shippers of independent product are looking for orders. Despite the dullness of the soft coal market there is a distinctly better feeling as the new year opens. Inquiries for both contract and spot coals are more numerous and buyers generally show indications of adding to their present reserves.

Coal Age Index as of Dec. 31 shows an advance of one point to 179 over the previous week. The corresponding average price was \$2.17. Slight increases in Mt. Olive, Standard, eastern and western Kentucky, Clearfield, Cambria-Somerset, Kanawha and Pocahontas districts were partly overcome by decreases in southern Illinois, Springfield and Indiana coals.

Production Takes Upward Turn

Output of soft coal increased to 10,545,000 net tons during the week ended Dec. 22 according to the Geological Survey, an advance of 607,000 tons over the previous week's production. In the corresponding week of 1922 the output was 10,138,000 net tons. Soft coal production for 1923 to Dec. 22 stands at 537,143,000 net tons, which is 117,370,000 tons ahead of the average production for 1919, 1921 and 1922, and 19,251,000 tons behind the average production of 1917, 1918 and 1920, the years of activity.

The holiday season affected the midwest markets last week. There was no action in domestic coals and little demand for steam sizes. While many mines closed down during the week between Christmas and New Year's, production exceeded the demand. The trade at St. Louis is doing little business in the cheaper grades of coal, but there is no demand for anthracite, smokeless coals or coke. Little activity is reported from

Kentucky, Duluth or Milwaukee. Buying is quiet in Ohio and the Pittsburgh district market continues in poor shape. An extremely quiet market is reported from New England, with buying and receipts in light volume.

The anthracite market lost much of its snap last week. While there is a good market for stove and chestnut coals the demand for the other sizes, with the possible exception of barley, is not active. Egg coal is in over supply with some shippers. Pea coal is rapidly accumulating and it was said that some of the larger companies were willing to make concessions to keep it moving. Quotations for this coal ranged as low as \$5.50 at Boston while the markets at New York and Philadelphia ranged around \$6. Cancellations of orders for high-priced coals are being received from Long Island and sections of New England. Output of anthracite amounted to 1,990,000 net tons, during the week ended Dec. 22. This was a decrease of approximately 23,000 tons when compared with the previous week.

The export market was quiet. Some inquiries were reported but comparatively little new business was reported as closed. Freight rates remained high. A slight increase in foreign business was reported at Hampton Roads. Dumpings for all accounts at Hampton Roads during the week ended Dec. 27 were 357,110 net tons, an increase of 1,183 tons when compared with the previous week.

Midwest Market Dormant

The week between Christmas and New Year's struck little life into the coal trade of the Midwest region. Domestic sizes of everything were without action and steam sizes were in light demand. Regardless of the fact that dozens of mines in Illinois, Indiana and Kentucky shut down before Christmas and expected to stay down until some day early in 1924, production was too great for the market. Cold weather seems to be a necessity if the trade in this region is to rise from the dumps.

Franklin county lump, rated at \$3.75 since the price drop

of Dec. 6, has softened until it is hard for association members to sell in the face of independent competition at \$3. Middle sizes have been selling at almost any price and screenings, though not in great volume, have sold in transit as low as \$1.20 though quoted at \$1.90 on the circulars. Central Illinois lump is soft at \$3 and screenings from that region waver from \$1.25 to \$1.50. There is little eastern coal coming into this general territory just now.

The usual holiday depression covers the entire Southern Illinois field and everything is quiet in Williamson and Franklin counties, with a little demand only for screenings and small nut. All mines have a surplus of domestic sizes and cutting the price does not seem to move them any. Railroad tonnage has eased up. Idle mines have strings of empty coal cars on their sidings and the tonnage loaded and billed moves promptly. Somewhat similar conditions prevail in the Jackson and DuQuoin fields.

St. Louis Trade Drags

Business is still dragging in St. Louis with weather above freezing. As a matter of fact, no season up to the present has equaled the end of 1923 for warm temperature. The

trade seem to be doing a little business for cheaper grades in smaller quantities and the finish of the year will be quiet, with practically no coal moving. There is no demand for anthracite, smokeless or coke and the higher grades of midwestern coals.

There is very little activity in the Western Kentucky fields, as most of the mines are reported as down with the idea of staying down until Jan. 2 or Jan. 7. Demand for

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

	1923			1922
	Dec. 31	Dec. 14	Dec. 17	Dec. 26
Index	179	178	181	349
Weighted average price	\$2.17	\$2.16	\$2.19	\$4.23

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

coal even including screenings is very dull. Screenings, however, bring 75c. to \$1 over prices of a few weeks back. Some of the Western Kentucky screenings are quoted at \$1.50 a ton, but highest sales found are \$1.25@ \$1.40. Mine run and prepared sizes show no change. Eastern Kentucky shows no material change from a week ago. Trade is light all around.

Northwest Is Quiet Too

A Duluth observer reports that the business is in a state of coma there and that nothing is maintaining the price circulars except an uncertainty as to the attitude the miners' union will take toward a strike April 1. In that city even domestic call is light in spite of a touch of winter.

There is no business in Milwaukee because of the failure of winter to deliver ice and snow but prices are steady. At the Twin Cities activity is lacking except among coal salesmen. Lignite from Dakota has had its effect and is getting some of the trade, even though the fuel value of this material is low.

It is estimated that 900,000 tons of soft coal and 240,000 tons of hard coal are on the docks at the Head-of-the-Lakes.

Little Doing in the West

Western markets are as light as those elsewhere. The surplus of coal that has been accumulating in the Kansas and Oklahoma fields is still on hand and prices have begun to soften in order to move it. During Christmas week the

average working time for the Southwest was two days but even that production could not all be sold.

In Utah and Colorado markets are light for everything and domestic sizes are generally soft. Dealers are not stocking now.

Ohio Markets Quiet

The market in Ohio was quiet during the holiday season. At Columbus buying was at a low point, consisting chiefly of small lots. Only a few large orders were reported as placed and the volume of business looked somewhat smaller than usual for this time of the year. Reduction in domestic consumption caused the closing of more Ohio mines and those operating are on a two to three days' weekly schedule. Retail prices have slumped in keeping with mine prices. In the Cincinnati market slack leads the market in demand, some of the activity coming through industrial and utility plants "covering" because of shut downs of their normal sources of supply. The market for both high and low volatile offerings is firm. Domestic coals are still in a bad way and retail dealers are curtailing their orders. There has been no change in the retail situation either as to price or demand. River business slackened on account of the holiday season. Demand at Cleveland was dull.

The Pittsburgh market continues in poor condition. Sales are hard to put through, there being little open market demand. There is some strike talk, but as yet there is very little disposition on the part of consumers to add to their stocks. Demand for domestic coals has been particularly poor on account of weather conditions. There is practically no demand at Buffalo. Slack is in better demand.

Buying Quiet in New England

In New England the year opens with an extremely quiet market. In no direction is there buying of any moment and receipts, both all-rail and by water, are very light. Scattering purchases that were made some weeks ago when prices were at a minimum have about ceased. The textile and other industries face a more encouraging prospect, but reserves are so large that no favorable reaction on coal is looked for until there is talk of possible labor troubles in April. Railroads and power companies are still receiving tonnage on old contracts, but the volume is notably less than during the first half of 1923. Generally there is an air of such complete dullness that the trade is all but discouraged.

At Hampton Roads the amount of coal at the piers is said to be less than at any time since June, but of course this situation is partly due to no work over the holidays. Quotations are firmer, but not so much because of any improvement in demand. No. 1 Navy acceptable grades can still be bought at \$4.60 per gross ton f.o.b. vessel, but several of the agencies are adhering to a \$4.75 level, preferring to keep the coal in the ground rather than net further losses. In consequence, on-car prices at this end are reasonably well maintained at \$5.75 to \$6 per gross ton for the same coals.

No Activity Along the Seaboard

The soft coal trade along the seaboard is quiet. There are numerous inquiries, and the prospects for better business early in January are bright. Buyers remained out of the market on account of inventory taking. At Philadelphia the trade at times seems to be a bit duller than usual. Consumers showed no interest and the early part of the new

year did not show anything better. Consumption was cut down, due to many mills closing on account of the holiday period, while the iron industry is not working anywhere near the capacity of two months ago. The Birmingham market is quiet. Inquiry is light for both steam and domestic coals. Production was slightly off, due to the holiday season, but there is plenty of coal above ground to meet all requirements.

Demand for Anthracite Easier

There is further easiness in the anthracite market at New York and Philadelphia. Demand fell off and quotations for independent domestic coals were easier. Pea coal is so plentiful that it is reported at New York that some of the large operating companies are cutting their prices in order

to keep the supply moving. At Philadelphia demand is poor for independent coals and the highest quoted prices are nominal. The softened market also hit the retail trade and one dealer has reduced his prices \$1 a ton. Stove and chestnut stocks are accumulating with almost every dealer having capacity stock of pea coal. The steam sizes are moving better, and barley is reasonably tight, some wholesale dealers being sold well ahead.

The coke market is steady. It is said that at least one first quarter contract and possibly two or three others, has been made at \$3.75, and other contracts have been made as high as \$4.40. Spot furnace coke remains at \$3.75@\$.4, and spot foundry coke at \$5@\$.50. A fair number of contracts for foundry coke have been made at \$6@\$.65.

Foreign Market And Export News

British Coal Market

The holiday season resulted in business being practically suspended in the South Wales coal market. Bunker supplies are limited and the demand for steam coals is somewhat easier.

British coal exports during the 11 months ended Nov. 30 were 73,575,713 tons as compared with 73,400,118 tons in the 12 months of 1913, the best previous record, according to official British Board of Trade statistics obtained by the Bankers Trust Co. of New York. Exports in 1922 were approximately 58,243,000 tons.

The Egyptian and Sudan governments are reported to be asking for bids for 200,000 tons of second admiralty and Monmouthshire coals by Feb. 5 and monthly deliveries beginning March. Other substantial inquiries are reported in the market.

Coal and Coke Exports and Imports

During November, 1923 the United States exported 369,429 tons of anthracite and 1,253,445 tons of bituminous coal, as compared with 440,608 tons of hard coal and 1,618,037 tons of soft coal in the corresponding month of 1922. Of the coal sent abroad last November Canada received 1,035,066 tons, Italy, 40,159 tons, France, 30,272 tons and Brazil 24,285 tons. Imports of coal during the same month was 8,690 tons of anthracite and 46,399 tons of bituminous as compared with 12,631 tons of hard coal and 366,423 tons of soft coal in November of 1922. Coke exports in November last amounted to 49,363 tons as compared with 38,397 tons in the previous November, with imports of 2,056 tons in November as compared with 8,543 tons in the corresponding month of the previous year.

Norwegian Coal Output

The annual report of the Great Norwegian Spitzbergen Coal Company for the year ended June 30, 1923, shows that production of coal for the year was 113,620 tons, and machinery installed since the close of the year is expected to bring the output up to 15,000 tons monthly. The quantity shipped during the period was 149,079 tons and the stock in hand at June 30 last 30,739 tons. The company's

largest customers are the Norwegian State Railroads and some large steamship owners.

French Coal Output Increases

In order to keep down the high cost of living the French authorities have asked the coal producing companies to reduce the increases recently made on the price of the various coals, the advance on sized coals to be 5 fr. instead of 10 fr. and on flaming coals 3 fr. instead of 5 fr.

During October the French mines produced 3,689,858 metric tons of coal as compared with 3,321,297 tons in September, and 190,225 tons of coke as compared with 181,648 tons in the previous month. The imports consisted of 1,935,821 tons of coal and lignite and 282,806 tons of coke. Imports in September were 2,619,831 tons of coal and lignite and 280,316 tons of coke. In October there was exported 121,915 tons of coal and lignite as compared with 156,137 tons in September; and 44,082 tons of coke, a decrease of 6,862 tons when compared with the previous month.

There was delivered to France and Luxemburg from the Ruhr during November 213,200 tons of coal, 298,800 tons of coke and 28,900 tons of briquets, a total of 540,900 tons, as compared with a total of 354,500 tons delivered in October.

Holiday Dullness at Hampton Roads

Business at Hampton Roads was unchanged last week, with the usual holiday dullness. Variations in price, if any, were slight, and little effort was made in the trade to push business until after Jan. 1.

Coastwise and bunker trade held their own, while a slight increase in foreign movement was noted. General improvement in the Virginian Ry. situation, in spite of the strike of trainmen, was one of the features of the market, and supplies of coal moved to port in a healthy state.

The tone of the market was weak, but shippers looked forward to immediate improvement in trade after the first of the year.

Private-Car Owners Present Strong Case In Assigned-Car Rehearing; Union Hints

Oral arguments in the assigned-car case were presented the Interstate Commerce Commission, Dec. 17, 18 and 19, and the rehearing granted by the commission after its original order of last spring, abolishing the practice stands submitted to the commission for decision. The commission has extended suspension of its original order until April 1, from Feb. 1, which was the last date fixed by the several previous extensions.

Private-car owners are considered to have presented a strong case to the commission. The steel interests were represented by an array of attorneys, the trend of whose arguments was that the steel industry cannot be operated economically without the use of private coal cars. A. G. Gutheim, representing a group of private-car owners who are consumers or shippers or both consumers and shippers, stated that private-car owners do not expect preferential movement of their cars by the carriers.

In behalf of the American Railway Association, Judge R. V. Fletcher stated that the railroads would agree that assigned cars be restricted to mines owned by railroads and to mines under contract with railroads for their entire year's output.

The construction of Paragraph 12 of Section 1 of the Interstate Commerce Act, which provides that all cars set at a mine shall be counted in the mine's rating, was brought into the case as to whether it should be considered literally or whether it really made into statute the principle of the Thayer case some years ago, in which the commission held in effect that it could rate mines from day to day. Commissioner C. B. Aitchison asked Judge Fletcher whether he considered this section a legal or an administrative matter. The attorney replied that he differed from some of his colleagues and considered it administrative. If the section be administrative, then there can be no appeal to the courts from any ruling of the commission under the section.

Individual attorneys representing several railroads which own mines argued that the commission has no jurisdiction over cars sent such mines by the owning roads.

E. S. Ballard, representing the National Coal Association, presented an argument in support of the commission's original ruling as to railroad cars. The association has remained neutral regarding the question of private cars. He further argued that by reason of some mines having assigned cars

and others in the same field lacking this system a competition for labor between mines was created which made the case one of discrimination in favor of the mine with the assigned cars, thus bringing the practice within Section 3 of the Interstate Commerce Act, dealing with discrimination.

A strong argument was presented by Van A. Bittner, special representative of John L. Lewis, president of the United Mine Workers. In his remarks, and also in the testimony he gave at the hearing in October, there was what some of the auditors interpreted as a hint that the United Mine Workers may attempt to abolish all forms of assigned cars in districts which are highly unionized. This was when Mr. Bittner called attention to the contract clause providing for an equal distribution of mine cars within the mine and stated that the U. M. W. stands for an equal distribution of railroad cars outside the mines. A full car supply at one mine and an inadequate supply at an adjoining mine causes unrest among the miners and makes for inequalities which all of the men would be glad to have ironed out, Mr. Bittner said.

Questioned as to whether the mine workers lost more time in 1922 from strikes or from lack of cars, Mr. Bittner said that the strike of 1922 was due in part to the assigned-car practice. Mr. Bittner emphasized in his argument what he stated in his October testimony that in his opinion and that of the officers of the United Mine Workers, the assigned-car practice has done more to overdevelop the coal industry than any other single factor.

Reading Financing Approved

An order of the Interstate Commerce Commission giving formal and final approval to the financing steps taken by the Reading Company to carry out the Supreme Court decree separating its railroad and anthracite interests was entered at Washington on Dec. 27. At the same time the Pennsylvania State Public Service Commission announced its approval of the merger of all the railroad corporations of the Reading system into one company to be known as the Reading Company.

Under the reorganization plan the Reading Company itself was authorized to take over and operate the Philadelphia & Reading R.R. system and its component railroad subsidiaries and to issue \$63,084,666 in new 4½ per cent gold bonds in exchange for old securities. The merger is the result of an

order of the U. S. District Court to segregate its coal and railroad business. As the holding company the Reading Company controls the Philadelphia & Reading Ry. Co. and twelve other underlying companies.

More Anthracite Rate Hearings

Announcement was made on Dec. 27 by the Interstate Commerce Commission that further hearings in its investigation of rates on anthracite and bituminous coal would be held in Washington before Chief Examiner Butler beginning Jan. 14. The investigation involves the question, among other things, of whether joint all-rail rates should be established from the southern West Virginia low-volatile fields to New England and North Atlantic States.

Would Dismiss Rate Complaint

Dismissal of a complaint brought by the Virginia Coal Operators' Association against the Aberdeen & Rockfish and other railroads was recommended on Dec. 27, by Attorney-Examiner W. B. Hunter in a report to the Interstate Commerce Commission. The report said the commission should find that rates on coal from the Appalachian and Dante districts in Virginia to points in North Carolina, South Carolina, Georgia and Florida, and rates from the Harlan County district in Kentucky to the same destinations were not unduly prejudicial as alleged.

Hearing on Higher N. Y. Rates

The Coal & Coke Committee of the Trunk Line Association announces a hearing Jan. 19 at 413 Liberty Street, New York City, on a carrier's proposal to increase the freight rates between Schenectady and Troy, N. Y., on anthracite, bituminous coal and coke, 13c. per net ton each. The present rates are \$1.13 each for anthracite and bituminous coal and \$1.26 for coke.

A hearing also is announced for the same day on a carrier's proposal to adjust bituminous coal rates from mines on the Pittsburgh & Lake Erie R.R., Bessemer & Lake Erie R.R., West Side Belt R.R., Pittsburgh & West Virginia Ry. and Baltimore & Ohio R.R. to Andover, Alfred, Almond, Hornell and other points on the Erie R.R. in New York State.

Coming Meetings

Tug River Coal Operators' Association. Annual meeting Jan. 4, 1924, Bluefield, W. Va. Secretary, C. C. Morfit, Welch, W. Va.

New England Wholesale Coal Association. Annual meeting Jan. 8, 1924, Boston, Mass. Secretary, R. S. Townsend, Boston, Mass.

Engineers' Society of Western Pennsylvania. Annual meeting Jan. 15, 1924, Blue Room, William Penn Hotel, Pittsburgh, Pa. Secretary, K. F. Treschow, Pittsburgh, Pa.

American Wood Preservers' Association. Annual meeting Jan. 15-17, 1924, Hotel Buehlebach, Kansas City, Mo. Secretary, P. R. Hicks, Chicago, Ill.

Northeast Kentucky Coal Association. Annual meeting Jan. 24, 1924, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

News Items From Field and Trade

KENTUCKY

The L. & N. railroad is reported to have bought properties at Ermine, three miles from Whiteburg, for the extension of yards there. This is expected to aid in the ready movement of coal from the Harlan and Hazard fields.

Of twenty-three cases decided by the Kentucky Workmen's Compensation Board on Dec. 18, all but four were in connection with accidents of employees of coal companies. In two coal company cases compensation was denied, but it was allowed in all of the others.

The 1923 tax assessment for Harlan County is \$24,302,131, as compared with an assessment of \$20,870,150 in 1922, which was increased by the supervisors to \$23,831,165. Coal has made the southeastern Kentucky district.

Willard R. Jillson has been asked by Governor Fields to continue as state geologist. Mr. Jillson was appointed under the Republican administration, but has handled his office so well that the new régime wishes to keep him on the job.

The Logan Pocahontas Fuel Co., Cincinnati, recently opened a branch sales office in the Inter Southern Building, Louisville, in charge of C. D. Calloway.

Fred M. Sackett, of the Byrne & Speed Coal Co., Louisville, headed a recent successful campaign to finance a Memorial Auditorium Fund of about \$1,500,000. He also is working hard on a campaign for erection of a \$7,000,000 bridge across the Ohio River to connect Louisville with Jeffersonville and New Albany. There are now three railroad bridges, all for steam lines, one having roadways, and two being utilized by electric lines as well.

ILLINOIS

Following the expenditure of \$15,000 for improvements, the Rutland coal mine, which was recently purchased by a group of business men from Ottawa, is expected to reopen soon for operation. Those interested are Lee O'Neil Browne, A. E. Butters, Fred T. Scherer, J. L. Bane, George L. Farnsworth and Louis Gowen.

T. H. Green, formerly superintendent of the mine at Girard, Ill., and more recently holding a similar position with the Standard Oil Co. mine at Shopper, until it recently closed down, has been named superintendent of the "Old Mine" at Auburn, which was recently purchased by the Leland Coal Co. of Chicago.

Drilling on a tract of land—the Hennessy farm—two miles east of Murphysboro is expected to develop a good acreage of No. 1 and No. 2 seam of coal unworked. It has been generally understood that all of this coal was under lease, but this farm was not included. It is on the electric line.

The new Shuler mine, at Alpha, has come into the realm of producing mines, as 100 tons of coal was hoisted Dec. 12, the first day the mine was operated. Charles Shuler, Jr., of Alpha is manager of the mine. Within the first month of operation the hoist will be raised to 300 tons of coal daily, with probable production of 1,000 tons a day when the mine is in full working condition.

The United Electric Coal Co. has acquired during the past year 2,500 acres of coal land within three miles of Cuba, at a cost of over \$300,000. A steel tippie and top works are under construction with a capacity of 4,000 tons per eight hours. Three steam shovels are at work. The total investment in this, one of the largest strip operations in the country, is about \$1,000,000. The Tiger Coal Co. also is opening up a strip mine near Cuba, with a capital invested of \$100,000.

The miners at the Valley Coal Co. mine, north of Duquoin, who sued for wages, have withdrawn their suits. The mine was being prepared for reopening under the direction of J. L. Mitchell of Royalton, who recently died. His death halted the work. The in-

vestors are hopeful of continuing the work, however.

The supply building containing the machine and blacksmith shops of Peabody No. 9 mine near Taylorville was destroyed by fire Christmas week, with a loss of about \$15,000. Defective wiring was the probable cause.

The Cripple Creek Coal Co., which has acquired leases to a large tract of land east of Galesburg, is arranging to have a core bore made on the land.

MINNESOTA

C. A. Bruce, secretary of the Twin City Coal Exchange, announced on Dec. 11 that the exchange will file a formal protest against the proposed increase in through rail rates on anthracite from the principal Pennsylvania mines to Minneapolis and other Northwestern points. The freight rate on anthracite, if changed, will mean an increased transportation cost of \$1.66 on a net ton of hard coal, Mr. Bruce said. Several other Northwestern organizations are planning to protest the proposed rail rate, according to Mr. Bruce.

Freight charges were more than twice the cost of coal recently bought by the City of Minneapolis for the crematory. A recent shipment of 712 tons of coal from Burton, Ill., cost at the mine a total of \$1,068.12, while the freight was \$2,342.64. Thus the coal cost \$1.50 a ton and the freight amounted to \$3.29 a ton.

NEW YORK

Announcement has been made of awards of coal contracts by the New York State Department of Purchases as follows: Shawnee Fuel Co., New York City, Binghamton State Hospital, 1,200 net tons slack, \$1.85 f.o.b. mine, and Central Islip State Hospital, 2,000 tons bituminous run of mine, \$1.63 per ton; Clark Coal & Coke Co., New York City, Elmira Reformatory, 1,200 tons bituminous run of mine, \$1.70 per net ton f.o.b. mine; Savage-Vail Corp., Indiana, Pa., Syracuse State School, 200 net tons run of mine, \$1.69, and Fidelity Fuel Co., New York City, Binghamton State Hospital, 5,000 net tons barley coal, \$1.20 per ton.

Jackson E. Reynolds, president of the First National Bank, has been elected to the board of managers of the Delaware, Lackawanna and Western R.R. to succeed Frank Rysavy, who has resigned. Mr. Reynolds is head of the Jackson E. Reynolds Syndicate, which recently bought the stock of the Lehigh & Wilkes-Barre Coal Co.

The Delaware, Lackawanna & Western Coal Co. on Dec. 26 declared an extra dividend of 5 per cent in addition to the regular quarterly distribution of 2½ per cent.

Stockholders of the Consolidation Coal Co. have approved changes in the certificate of incorporation permitting a change in the par value of the company's common stock and also the creation of an issue of \$10,000,000 7 per cent cumulative preferred stock, the proceeds of which will be used to reimburse the treasury of the company for capital expenditures and the acquisition of new properties.

The votes of the members of the American Institute of Mining and Metallurgical Engineers for officers and directors for the ensuing year are to be counted Feb. 13. Ballots to be counted must reach the secretary on or before Feb. 12. The official ballot of the Committee on Nominations is: William Kelly, director and president; E. DeGolyer, director and vice president; Charles W. Merrill, director and vice president; directors, R. V. Norris, George Otis Smith, P. E. Butler, Bertram D. Quarrie and L. D. Ricketts. Members will vote also to amend the constitution by making a life membership cost \$225 instead of \$150, and also that a junior associate member may remain such not longer than six years, the period to begin Jan. 1 of the year of election. The article now in force reads that a junior associate member may remain such not longer than five years after leaving an engineering school.

OHIO

An issue of \$2,000,000 collateral trust 6 per cent serial gold notes of The Houston Collieries Co., maturing 1924-1933, has been purchased by a Cincinnati financial syndicate. The notes will be offered in the public market at prices to yield 5.75 to 6.50 per cent according to the various maturities.

John Emslie, manager of the Creech Fuel Co., Fred Gore, sales manager of the Blue Diamond Coal Sales Co., and Ernie Howe, manager of the Pocahontas Fuel Co., were elected directors of the Cincinnati Coal Exchange at the annual election held at the Chamber of Commerce.

The Virginia & Kentucky Coal Co. has been incorporated by J. Bert Shumate and Fred Dunker, formerly of the Pocahontas-Kanawha Coal Co., of Dayton. Offices have been taken on the 11th floor of the First National Bank Building in Cincinnati.

W. M. Tobin, who has been fuel inspector for the Milwaukee Coke & Gas Co., for some time at Cincinnati, has been added to the sales force of the Imperial Coal Sales Co., of that city.

PENNSYLVANIA

The Lehigh & Wilkes-Barre Corporation, the holding company for Lehigh & Wilkes-Barre Coal Co., has sold \$10,000,000 5½-per cent collateral trust bonds, dated Jan. 2, 1924. The corporation owns 149,788 shares of the outstanding capital stock of the coal company, formerly the property of the Central Railroad of New Jersey and ordered sold by the courts. These shares are assigned to The First National Bank of New York City, as trustee, of which Jackson E. Reynolds, is president as collateral security for the payment of the principal and interest of the bonds. C. F. Huber is president of the corporation and also president of the coal company. The board of directors of the coal company paid on Dec. 24 an extra cash dividend of \$40 per share on its capital stock.

Judge Thomas F. Bailey at Huntingdon, on Dec. 26 appointed Andrew S. Webb, of Philadelphia, receiver for the Joseph E. Thropp Co., Inc., which operates iron and coal mines and coke ovens in Pennsylvania and Virginia. The assets were given as \$2,400,000, and the liabilities, \$1,300,000, with quick assets of only \$675,000. The slump in the iron business and inability to obtain additional working capital were given as reasons for the receivership. The appointment was made on a petition of creditors although officials of the corporation declared it was solvent and that all its indebtedness would be paid. The business will be continued by the receiver, whose bond was fixed at \$100,000.

A charter for the Philadelphia & Reading Coal & Iron Corporation was filed at the State Department at Dover, Del., Dec. 20. The new concern was created as a result of the segregation of the Reading Company properties, and will take over the interests of the Philadelphia & Reading Coal & Iron Co. and the Reading Iron Co. The new corporation is authorized to issue 1,400,000 shares of capital stock, without nominal or par value. The incorporators are William J. Richards, Pottsville, Pa., president of the old company; Robert J. Montgomery, Philadelphia, vice president and general coal agent, and William H. MacEwan, Haverford, Pa., vice president and secretary.

Fire, which is believed to have been started by an overheated journal, on Dec. 24, destroyed the washery of the Avoca Coal Co. in Avoca, which is valued at about \$70,000. Early this summer the owners spent \$20,000 in repairing and rebuilding the structure. The loss is partly covered by insurance, it is understood.

WISCONSIN

A special committee of the School Board of Milwaukee, is engaged in studying the merits of Western and Eastern soft coal with a view to a possible trial of the former. Heretofore all city contracts have been let to dock companies handling Eastern coal.

WASHINGTON

The Chicago Pneumatic Tool Co. New York, announces the appointment of the General Machinery Co. of Spokane, Washington as their agents in the eastern part of the State of Washington and northern part of Idaho.

WEST VIRGINIA

The W. M. Ritter Lumber Co., of Columbus, Ohio, has acquired by purchase in fee simple a tract of approximately 67,000 acres of coal and timber lands in Wyoming County, W. Va., which is located near the Virginian R.R. The purchase carried a consideration of \$1,600,000. The entire tract is underlaid with coal varying from 36 in. to 72 in. thick and 28,000 acres of which has smokeless grades. The other is about equally divided between the New River and Kanawha veins. The purchase was made from the Dalton-Kelley-Crane interests.

Formal organization of the Sullivan Pocahontas Coal Co. was effected at a meeting held at Tralee when the following officers were elected: J. C. Sullivan, president and treasurer; Dr. J. A. Wood, of Pratt, vice-president; J. B. Frank, of Tralee, secretary. On the board of directors are the above-named officers and the following: Dr. J. H. Craft, of Springing; James Gorman, of Lynchburg, Va.; R. J. Hancock, of Lynchburg, and H. W. McNeil, of Tralee.

Major Appleyard, of England, who owns extensive mining interests in the Durham district of Great Britain, in company with several associates inspected the mines in the Pocahontas district recently.

A dissolution certificate has been filed with the Secretary of State of West Virginia by the Balkan Coal Co., the main offices of which are in Philadelphia. The Loop Coal Co., of Elkins, also has filed notice of dissolution with the Secretary of State of West Virginia.

Thomas H. Laulis, of Shinnston; Charles E. Pitter, of Fairmont, and associates have chartered the Laurel Run Coal Co., with \$250,000 capital for developing coal land on Laurel Run.

It was only after the Charter of Local 4,047, at Grant Town, had been revoked that the five hundred miners employed at Federal Mine No. 1 of the New England Fuel & Transportation Co. returned to work after having been engaged in an illegal strike from Dec. 11 to 15.

E. Macon Jones has resigned his position with the Twin States Fuel Co. of Hington to become assistant to the Western manager of the Chesapeake & Virginian Fuel Co., of Cincinnati.

The Howard Thacker Coal Co. has just been organized by McDowell County coal men, with a capital stock of \$25,000. Headquarters of the company are to be at Welch. Incorporators are: George W. Lambert, James P. Flannagan, Thomas J. Flannagan, E. W. Howard and J. N. Harman, Jr.

The Wheeling Steel Corporation has completed arrangements to purchase a large tract of coal land in Mason County, extending from a point near New Haven to Letart, along the Ohio River. This coal is said to be in the Pittsburgh and Freeport seams.

Announcement has been made that the Raleigh Fire Creek Coal, the Pickshin Coal Co., Tommy Creek Coal Co., Wood-Sullivan Coal Co., Barkers Creek Coal Co., Hartly Coal Co. and the Mead Pocahontas Coal Co. have been merged into the Sullivan Pocahontas Coal Co. The mines of the various individual companies are located on the Virginian, Chesapeake & Ohio and the Norfolk & Western Rwy. The headquarters of the new company will be at Tralee.

The Coal River Co-operative Coal Co. has been organized by Buckhannon people to engage in the development of coal lands in Upshur and other counties of the state. The new concern is capitalized at \$50,000. Identified with the new concern are I. G. Cutright, G. C. Christner, C. A. Winchester, G. E. Stearns and D. A. Barton.

In connection with the visit of three members of the international board of the United Mine Workers to Charleston recently C. F. Keeney denies that the committee was sent to investigate the affairs of the district. The district president said that the committee came to confer with D. C. Kennedy, secretary of the Kanawha Coal Operators Association, and to investigate complaints of inequality. It was explained by Keeney that the inequalities referred to differences in cost of production in different mines and that the operators asked that the inequalities be investigated with a view to appealing for a revision in their wage contracts with the miners.

The Lundale Mining Institute held its annual banquet at the Lundale Club late in December, marking the fifth successful year of the Institute. About three hundred members as well as prominent mining officials and railroad men attended. Among the speakers were George M. Jones president of the Logan County Coal Corporation; Walter R. Thurmond, president of the

Thurmond and Argyle Coal companies, and J. T. Ryan, vice-president and general manager of the Mines Safety Appliance Co., of Pittsburgh, Pa.

The Holly Elk Coal Co., has been organized at Clarksburg with \$250,000 capital and A. C. McIntyre president and general manager, for development of 1,500 acres of coal land in the Eagle and Sewell seams on Elk River in Webster County.

WASHINGTON, D. C.

John B. Pratt has resigned the editorship of *Coal Review* to take effect Jan. 1, after two years in that post. It is understood that he will re-enter the journalistic field with which he was actively connected prior to his becoming associated with the coal industry, four years ago. In 1919, when the Bituminous Operators Committee of the Central Competitive Field was formed to present the operators' case before the Bituminous Coal Commission, he was secretary of that committee and in charge of its publicity work. Early in 1920 he became director of publicity for the National Coal Association. In July, 1921, he was also made editor of *Coal Review*.

The Board of Directors of the National Coal Association will hold their quarterly meeting in Washington, D. C., on Wednesday, Jan. 9, 1924, to consider the work of the association for the past six months. A number of important committee meetings will be held Jan. 8, among them the Government Relations Committee, the Bituminous Operators' Special Committee and the secretaries' of local associations. All of these committees will consider propositions of importance to the industry with a view to making recommendations to the directors' meeting.

CANADA

Output of coal from Canadian mines during September, according to the Dominion Bureau of Statistics, amounted to 1,218,000 net tons, a decrease of 24 per cent from the tonnage for the previous month and 21 per cent from the average for the month for the three preceding years. The output showed decreases of 162,000 tons in Nova Scotia, 171,000 tons in Alberta, 40,000 tons in British Columbia and 1,000 tons in New Brunswick. In Saskatchewan there was an increase of 1,000 tons. The cumulative output from all mines for the first nine months of 1923 amounted to 12,609,000 tons, an increase of 16 per cent over the preceding three-year average for the same period. Comparison of September and August figures covering the total importation of coal from the United States and Great Britain showed a decrease of 23 per cent. September imports amounted to 2,125,000 tons, while in August 2,746,000 tons was brought in. The September importations this year were 38 per cent greater than the three-year average for the month. During the month 78,100 tons was imported from Great Britain. Total importation of all coal for the nine months of 1923 was 17,518,900 tons, an increase of 52 per cent over the preceding three-year average for the same period. Imports of anthracite for September totalled 328,800 tons. This was 33 per cent less than in August, but 29 per cent higher than the three-year average for the month. Anthracite imported from the United States amounted to 287,900 tons, while 41,000 tons came from Great Britain during the month. Classified by grades, 301,100 tons was of egg, grate, stove, etc., sizes, and the balance 27,700 tons of buckwheat and rice sizes. The total amount of anthracite imported during the nine months of 1923 was 4,004,700 tons, an increase of 42 per cent over the three-year average for this period. The exports of Canadian coal for the month of September were 13 per cent less than in August. The quantities were: September 90,600 tons, August 103,500 tons. Comparison of the September exports with the preceding three-year average showed a decrease of 52 per cent.

J. E. McLurg has been appointed vice-president of the British Empire Steel Corporation in charge of operations of all constituent companies with headquarters at Sydney, N. S., to fill the vacancy caused by the resignation of D. H. McDougall. Mr. McLurg has been for some years general manager of Halifax Shipyards, Ltd.

The briquetting plant at Bienfait, Sask., being at present closed down for want of funds, two carloads of carbonized lignite were shipped for further treatment to the Babcock plant at Hebron, N. D. The completed briquettes have been re-shipped to Canada, and the members of the Lignite Utilization Board state that they are of first-class quality and that the success of the experiment has been demonstrated.

Association Activities

At a recent meeting of directors the Alabama Mining Institute re-elected Frank Nelson, Jr., as president for the ensuing year. Other officials named were George F. Peter, vice-president; Charles A. Moffett, chairman of the board, and James L. Davidson was re-elected secretary-treasurer, a position he has acceptably filled for several terms. The board of directors includes G. B. McCormack, J. W. McQueen, A. B. Aldridge, J. B. McClary, C. T. Fairbairn, S. L. Yerkes, George W. Connors, C. F. DeBardeleben and Charles A. Moffett.

At the annual meeting of the Philadelphia Coal Exchange, held Dec. 20, the following officers were elected to serve during 1924: President, Maurice J. Crean; Vice President, Samuel B. Crowell; Secretary-Treasurer, Charles K. Scull; Directors (to serve for three years), Arthur L. Cohn, Martin F. Connor, Samuel E. Donaghy, John E. Lloyd and Harry E. Strathmann. There are ten holdover directors, five for one year and five for two years.

The New River Coal Operators Association held its annual meeting at Mt. Hope Dec. 20 with a large attendance, companies shipping more than 95 per cent of the coal tonnage produced in the field being represented. Transportation and the effort to obtain an adjustment of rail rates to points north and east of the Potomac came in for discussion and there were addresses by H. L. Gandy, secretary of the National Coal Association; A. M. Belcher, attorney for the operators in the Logan armed march cases; Robert M. Lambie, chief of the West Virginia Department of Mines; A. M. Dudley, general freight agent of the Chesapeake & Ohio, and H. F. Brown, superintendent of the Hinton division of the same road. S. A. Scott, of the New River company, was chosen president; Ernest E. Chilson, general manager of the Raleigh Coal & Coke Co., vice president; P. M. Snyder, of Mt. Hope, treasurer; S. C. Higgins of Mt. Hope, secretary and traffic manager; members of the executive board, William McKell, president of the McKell Coal & Coke Co.; R. E. Taggart, of the Stonegate Coal & Coke Co.; G. H. Caperton, New River Coal Co., and M. L. Garvey, of the Maryland and New River Coal Co.

Obituary

Julian Burrell Huff, coal operator and noted polo player, died on Dec. 24 at Philadelphia, Pa. Injuries received on the polo field are believed by physicians to have brought about his death, the immediate cause of which was a cerebral hemorrhage. Mr. Huff was president of the Keystone Coal & Coke Co., the Latrobe-Connellsville Coal Co., the Mountain Coal Co., the Acme Gas & Coal Co. and several other gas and coal companies in western Pennsylvania.

I. N. Hanson, industrial builder and early developer in the coal fields of Alabama, died Dec. 16, at Bayou Le Batre, Miss., after a long illness. Mr. Hanson was a stockholder and director of the DeBardeleben Coal Corporation. He was a brother of the late Major J. F. Hanson, president of the Central of Georgia Ry. Mr. Hanson was 76 years of age and unmarried.

Lyman M. Graham, 78, retired president of the McLean County Coal Co., of Bloomington, Ill., died recently at his home after a long illness. Starting as a bookkeeper he served his company for 55 years of continuous service, retiring on Jan. 3, 1923. The firm was organized in 1867.

L. L. Legg, director of the Standard Coal Co. and Standard Fuel Co., Salt Lake City, and widely known in the coal-mining industry of Utah, died at Riverside, Cal., recently. He was born in Illinois in 1871.

Charles A. Tribbey, aged 49, died at his home, near Cincinnati, Ohio, Dec. 20. He started in many years ago with the White Oak Coal Co. and rose to be its manager. When that company went out of business, about nine years ago, he was associated with his brothers-in-law connected with the Ulland Coal Co. and in charge of its wholesale department. Six years ago, after the purchase of mines in northeastern Tennessee and southeastern Kentucky, he formed the Tribbey Coal Co. About four years ago he suffered a stroke of paralysis, which failed to yield to treatment and he retired two years ago. The funeral was held Dec. 22.

New Equipment

Riveting Air Hammer

A pneumatic riveting hammer of new type, with many improved and economical features, has been perfected and is now being offered by the Ingersoll-Rand Co., 11 Broadway, New York City. The outstanding features of this new riveter include bolted construction for holding the handle to the barrel, heavy section valve with liberal bearing surfaces; combination poppet and piston type throttle valve; power in excess of all ordinary requirements;

EASILY CONTROLLED AIR HAMMER

This device is made in sizes ranging from 5-in. to 9-in. stroke.

low air consumption and exceptionally easy operation.

The new style hammers are manufactured in three styles, A, B, and C, and are available in a complete range of sizes from a 5-in. to a 9-in. stroke. Each size of this riveter can be purchased with any one of three types of barrels and with either outside or inside trigger handles.

The standard "A" type has a barrel machined to accommodate a rivet set clip only and is furnished on all orders which do not specify either a bridge type or retainer type barrel. Three alloy steel bolts of substantial size, fitted with lock washers, hold the handle to the barrel. This is an exclusive feature of these hammers and enables one to take them apart anywhere for inspection or cleaning with the aid of only a wrench; no vise, crowbar or other tools are necessary.

The throttle valve (except on inside trigger handles) is a combination of the piston and poppet types, having the nicety of control of the piston valve and the freedom from leakage of the poppet type. The beveled seat will remain tight throughout the life of the tool, preventing leakage. The throttle lever, or trigger, is made in one piece from special heat-treated spring steel and has a long bearing in the handle. The control is sensitive, ranging from a light tap to a heavy blow, entirely at the will of the operator.

The valve is a sturdy sleeve made from special alloy steel. It has liberal bearing surfaces and its walls are free from holes or ports, which so often are the starting points for checks or cracks. It operates in a valve box of strong construction, located in the head of the barrel. The valve box is constructed with a solid end which makes

it possible to take it apart easily by the use of a piston for the removal of the valve, without recourse to the use of a screwdriver or similar instrument with subsequent danger of injury. This construction also insures a compression chamber in the valve box which cushions the piston on the return stroke and prevents the piston from striking the handle.

The handles are of high quality steel, drop forged to a shape that fits the hand and are sand-blast finished to give an excellent grip. Either outside or inside trigger handles can be furnished, although the outside type is standard. The exhaust is through the side of the barrel near the handle and can be deflected in any direction desired by the operator, by merely turning the deflector.

They are fast, hard-hitting hammers, yet have less "kick-back" than usual and consume less air. Due, primarily, to the bolted-handle construction, they are lighter in the handle end and consequently are better balanced and easier holding, especially when used in a horizontal or inverted position.

Briquet Binder

A new binder for coal briquets has been developed by the Robeson Process Co., Fifth Avenue, New York City, which the company asserts may be easily handled, is strong, combustible, and burns without offensive characteristics. This substance is called glutrin, which is a trade name used to design-

nate a material made from a product of the pulp mill in the manufacture of paper.

In appearance this material is a liquid of about the consistency of thin molasses. It is unaffected by heat or cold in handling and shipping, is strongly adhesive and will sustain the burden of the fire until the entire briquet is consumed. Being also both smokeless and odorless, its suitability for domestic use is apparent.

Air-Swept Dry Pulverizing Mill Suitable for Coal

The principle of the air-swept mill is to sift the superfluous material from the mass as and when it is finished to the desired fineness. It is a device which will be appreciated by everyone interested in the dry grinding of products, among which is pulverized coal for power purposes.

Unusual features of the plant are the tower drier, which consists of a system of baffling and requires no power to operate it, and the fact that it has no discharge lifters and no means of extracting the material except the velocity of the air through the mill. It is equipped with an air box at the feed end and one at the discharge end. These boxes have valves on both sides so that the quantity of air delivered at the feed end and taken out at the discharge end regulates absolutely the fineness of the product discharged.

The valves on the air box at the discharge end of the mill can be regulated so that the elevating power of the fan is maintained for lifting the material through the cyclones to the bin, as is evidenced by the sifting test. The complete mill equipment is manufactured by Kennedy-Van Saun Mfg. & Eng. Corp., 50 Church St., New York City.

PULVERIZING-MILL EQUIPMENT

Regulation of the air through the mill carries away the ground material when pulverized to the desired fineness.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, Editor

Volume 25

NEW YORK, JANUARY 10, 1924

Number 2

IT IS with much regret that the publishers announce the resignation, as editor of *Coal Age*, of C. E. Leshner, who has so ably conducted the paper during the last three years. His loss will be keenly felt by *Coal Age* and by the industry, for Mr. Leshner, through his clear and forceful discussions, furnished a leadership much needed in these troublesome times in coal production. Mr. Leshner will become assistant to the president of the Pittsburgh Coal Co., the largest producer of bituminous coal in this country.

No changes will be made in the editorial staff. The present organization, trained and inspired by Mr. Leshner, is not only competent to "carry on" but realizes that the opportunity for service to the industry was never greater. *Coal Age* is in a particularly favorable position to help. It has a sympathetic attitude toward the problems of the industry; it commands the industry's respect and confidence. At the same time it is sufficiently detached to see the problems with an impartial eye and to bring to the industry the counsel that results from an appreciation of the industry's obligations to the public. Such a task is not always a pleasant one, but the good of the industry requires that *Coal Age* have its courage high and speak without fear.

R. Dawson Hall, who has been with *Coal Age* since its establishment and who has an intimate acquaintance with the personnel and problems of the coal mining industry, will be in editorial charge of the paper, effective Jan. 18.

Speaking for the editorial staff, the publishers have no hesitancy in assuring the coal industry a service worthy of the respect and confidence in which *Coal Age* is held—a respect and confidence which have been heightened during Mr. Leshner's editorship and which he leaves as a precious heritage and a continuing inspiration to those who succeed him.

THE PUBLISHERS.

FOR the confidence and understanding sympathy of the many friends and readers who have contributed so much to the success of *Coal Age* and to the pleasantness of my editorship in the past few years I am sincerely appreciative. There is a peculiar satisfaction attaching to such work as this that brings one into intimate relationship with the real forces within an industry as large and important as coal.

Coal Age is an institution in the coal industry; my coming and going are but incidents in its history. It has traditions of service and ideals of greater and greater helpfulness to its field. To have been associated with *Coal Age* has been an inspiration and an honor. When next week I relinquish the reins to my present associates and step out of the roll of observer into that, where inclination and opportunity have led me, of active participation in the coal industry, it will be with more than perfunctory regret.

For Mr. Hall, who succeeds me, and his associates I bespeak the good will and co-operation of the men in the industry that it has been my good fortune to enjoy. Their efforts through that inanimate yet living thing, the printed page, to point the way and indeed inspire the men of the coal industry to better methods, safer practices and a larger appreciation of public service cannot bear full fruit without active participation by those in the daily grind of production and distribution.

It is fitting also to record here that which may not be known and appreciated by all, that *Coal Age* is a free agent, its editorial policies untrammelled by special interests, unhampered by exigencies of business policy. *Coal Age* does not speak for the coal industry, but as one of the family it speaks to coal men. To such a journal, as one of the industry, I pledge my loyal support, urging on my new colleagues my belief that *Coal Age* will be valuable as a tool in their work in proportion as they help to make it so.

C. E. LESHER, Editor.

Who Will Urge a Secretary of Mines?

PERENNIALY there rises the question of a Department of Mines. Probably the first recorded effort in that direction was by the American Mining Congress nearly fifteen years ago, when the present Bureau of Mines was authorized and organized. There is argued in favor of a Cabinet portfolio for mining that mining and agriculture are the country's two largest basic industries, that the farmers have a Cabinet officer, and that therefore the miners should have one. Senator Oddie, of Nevada, is advancing the idea strongly this winter. He is chairman of the Senate Committee on Mines and Mining and has given life to that committee by having maneuvered the reference of coal bills to it.

We believe that mining is of sufficient importance to rank with agriculture and would much rather have a Department of Mines to look after coal than have a section in the Interstate Commerce Commission regulate the industry. The railroads rank as high in national importance as mining but they have no Cabinet representative.

We sympathize with the effort Senator Oddie is making. We wish it success. But we cannot refrain from

noting that departments with Cabinet officers at their head are not created unless a large and influential section of the public demands that sort of recognition. The farmers have their department because they have the influence—the votes, if you please—and demanded the service and the representation that flows from a Cabinet official. Labor also has such a department; likewise general industry. When the public wants to regulate an industry it does not demand of its chosen representatives at Washington that they create a department for that purpose, but rather a commission.

The public, and Congress, look on coal as an industry to be regulated. Not until they see coal as an industry to be helped—not until mining comes into higher esteem—can we hope for the happy fruition of Senator Oddie's plan.

Preparing an Alibi

ELLIS SEARLES, unofficial spokesman for John L. Lewis, is reported in the press to have said recently that "a large and powerful element among the coal operators is doing everything within its power to force a strike next April." Chief among those assailed by

Mr. Searles as seeking to tie up the union mines are the "non-union operators of West Virginia, Kentucky, Maryland and southern Pennsylvania. If they can so manipulate matters as to cause a shutdown of the union mines north of the Ohio River, the non-union mines can then continue at work." He asserted that the United Mine Workers do not want a strike, but a continuity of employment.

That the union does not want a strike but plenty of work at the present scale we believe, if by union one means the controlling administration. But there is not plenty of work even at this time, there has not been plenty of work, and there is not going to be plenty of work for the union miners at the present scale. Sooner or later the non-union fields will cut into the union markets with lower costs. So it is obvious that the United Mine Workers cannot have what it desires—plenty of work at the present scale. What will be the second best desire of the United Mine Workers when the consciousness of this fact sinks deeply?

If Lewis elects to have a strike, on what grounds will he justify it? In 1922 he used the shibboleth of the "broken contract." Apparently this year he is laying the foundation well in advance, as he did two years ago, but this time he is preparing to put the blame on the non-union operator. If the outcome of the present uncertain situation is a strike—and why call it softly a suspension?—then, according to Mr. Lewis, it will be the non-union producer that brought it about. Just what this insidious individual has done, is doing, or is about to do, Mr. Searles has not said.

About all that the non-union operator can do is to compete with the union operator and annex all of his business that he can. It is of course a fine thing in a business way for the non-union fields to have the union so conduct itself as to make the organized fields a standby source of fuel for the nation, working when demand is good and shutting down when the market is stocked up. The non-union fields thus have the opportunity for more or less continuous operation, a position buttressed by their ability to adjust costs with fluctuations in the market.

But we think it most unfair for Mr. Lewis to prime Mr. Searles to go about telling the country that those awful non-union operators are planning to have a strike in the union fields, when the only people who can force a strike there are the union miners or the union operators. Are the union fields so weak that the *hope* that non-union producers are said to entertain that there will be a strike constitutes "a powerful influence working for a strike?"

The matter, after all, is clear enough. The United Mine Workers would like nothing better than a renewal of the present scale, and to get that will doubtless ask more in order to have a trading basis. The union operators would welcome a reduction in wages and therefore in costs so as to be able to meet non-union competition, but they have every reason to believe that they cannot accomplish that, even if they put the matter to the test of a prolonged strike. There is no suggestion, so far, of their asking for a reduction. Why, then, the early attempt to establish the alibi? Is President Lewis fearful that he cannot hold his men in line, that they will not be satisfied with a renewal and that there may be a strike despite his efforts to the contrary? Who in the coming summer can longer stand the gaff of short working time, the union miners or the union operators?

Small Cars, Low Tonnage

ONE cannot but feel in entire accord with many of John T. Ryan's reactions in regard to European conditions, as expressed in the article we publish this week. No one can fail to admire the conservational methods of Europe, the saving of coal, to say nothing of the low death rate per man employed if not per ton of product.

However, we cannot see how Europe is justified in its small mine cars. A redoubtable Belgian authority has assured us that the roadways in the mines of that country are large enough to permit of cars of large size and that larger equipment would be justified. That, however, we are informed, is not true of at least many mines in Great Britain.

Standardization is not so necessary in mining as in railroading. In the latter the equipment in many instances must be light enough to pass over the bridges of other railroads and small enough to clear the tunnels of other companies. But each mine is a unit in itself except in so far as it may be cheaper to buy equipment of the size that is being most generally manufactured.

Consequently it would seem that at any mine a larger car might be used, provided that the work of enlarging the shaft and roadways would not be so costly as to make it impossible within a few years to recover the expenditure by savings in haulage, car handling and ventilation, keeping in view always the larger tonnages that bigger cars would make possible.

We are willing to accept the suggestion that in some British mines such alterations as would make the larger car possible would be, if not prohibitive, at least of problematic advantage, especially where the seams are thin and high headings would involve the handling of much rock. But this would not apply to new mines. Great Britain is not opening these as frequently as the United States—fortunately perhaps for that Kingdom—but nevertheless one would expect to see progress, for are not the mines in the deeper deposits in Yorkshire and all those in Kent relatively new? Here is a chance to show what large cars could do.

Great Britain is ahead of the United States in the use of face and roadway conveyors, partly because of the mining of thin seams. The coal, accordingly, frequently is brought to the main roadways by conveyors. On these roadways, therefore, surely big cars could be used. It seems likely that the United States will be induced to put larger cars than ever into its mines in order to keep the conveyors moving with less frequent delays as soon as such means of transportation are introduced. The use of conveyors, however, does not seem to have had any such effect on the methods of our British cousins.

Would that some Sir Isambard Brunel were alive today to urge on the British people the motto which Michael Angelo gave to Raphael in the latter's early years—"Amplius"—so that the British would in this matter seek larger standards of construction.

It will be remembered that Brunel was the man who gave the railroads of Great Britain, for a while, and in spots only, the six-foot gage. He was ahead of his time. Even the United States after trying it gave it up, but today many railroads would wish it had succeeded and the standard gage had failed. Fortunately in mining our car sizes are not standardized in the same way as in railroading.

Novel Application of Dynamic Braking On Large Slope Hoist

Peculiar Requirements of Hoisting and Lowering Speeds Under Widely Differing Loads While Handling Coal, Supplies and Men Necessitate Unusual Type of Control—
Success of Installation Proves Efficacy of Plan

BY R. W. MCNEILL

General Engineering Department
Westinghouse Electric & Manufacturing Co.

EVERY electric hoisting installation is a problem in itself and requires careful study for the best solution. The type of equipment which may be the best for one set of conditions may prove unsuited or uneconomical for a different set of conditions. To decide each problem on its merits is the engineer's problem. In most cases some particular feature of operation or of power supply will be the deciding factor in the choice of the type of equipment to be used. In the case of the hoist for the Packer No. 2 slope of the Lehigh Valley Coal Co., at Shenandoah, Pa., the requirements were such as to impose several unusual operating conditions and the equipment finally selected to meet these conditions makes use of many features not commonly used with electric mine hoists.

The Packer No. 2 slope is in what is known as the Mammoth Vein. The angle of inclination as compared to the horizontal is not uniform, varying between 36 and 45 deg. It is of the single-compartment type equipped with a single track on which cars are hoisted and lowered by a single-drum single-cable hoist to handle men and material. A cross-section of the mine slope is shown in Fig. 1. Material is handled two cars per trip, the maximum weight of the loaded trip being 31,000 lb. and the weight of an empty trip being 9,600 lb. Men also are hoisted in two cars per trip, ten men in each car. Coal, rock and empty cars are handled at a speed of approximately 1,200 ft. per minute while men are handled at approximately 500 ft. per minute. All coal and rock, whether mined above or below the second level, is landed on this level and taken out of

the mine through a tunnel which intersects the slope at this point. Men are handled from the surface to the different levels and are brought to the surface on completion of the shift.

From the foregoing it is readily seen that the operating conditions are quite different from the usual mine hoist in that operation is "unbalanced" at all times and that widely varying loads must be handled in the two directions of travel. To these conditions there was added the stipulation that the operating speed should at all times be completely under the control of the operator with a minimum use of mechanical braking.

Selection of the mechanical parts of the hoist was a fairly simple problem, for the mechanical construction of the hoist was fairly well fixed by the operating conditions as a single-drum geared machine with mechanical brakes of sufficient capacity to hold the load safely in case of power failure, and to take care of a moderate amount of braking without overheating.

Selection of the proper electrical equipment for operation of the hoist was not so simple. Power for operation of the electrical equipment was available at 2,200 volts, 3 phase, 60 cycles, and while it would have been a comparatively simple matter to obtain the required operating characteristics by using a direct-current hoist motor and motor-generator set, using Ward-Leonard control, this would have necessitated a large motor-generator for supplying power to the hoist motor and the outfit would have had a rather high first cost and would have been uneconomical in the use of power.

It was thought best, therefore, to investigate to determine if the required characteristics could not be obtained with a wound rotor induction motor and special control equipment. Satisfactory operation in the hoisting direction did not present any particular prob-

Headpiece shows general view of hoist building. Purchased power is supplied at 66,000 volts and stepped down to 2,300 volts. Ample provision has been made for increasing the transformer capacity. On the extreme left is shown a distributing tower designed to supply other mines in this region also mined under lease from the Girard estate.

FIG. 1—SECTION THROUGH PACKER NO. 2 SLOPE

Coal hoisting is carried on from the third, fourth and fifth levels to the second level. Supplies and men are hoisted between the various levels and the surface. Occasionally heavily loaded rock cars are hoisted to the surface, thus placing a heavy load upon the hoist.

lem with an induction motor other than that the motor be of sufficient capacity to handle the heaviest loads at full speed, as the problem of obtaining reduced speeds with light loads was simply a question of external resistance and control points to give the required speeds at the different torques necessary.

To obtain satisfactory operating characteristics in the lowering direction was a more perplexing problem. There were available two ways of obtaining electrical braking and speed control with the overhauling loads encountered in lowering. The first and most obvious method was to lower against the torque of the motor, with power applied to the motor primary by the same switches as for the hoisting direction and regulated by the secondary resistance to keep the braking torque of the motor balanced against the overhauling torque produced by the descending load to obtain speed control.

The second method and the one finally adopted makes use of direct-current excitation on the stator of the induction motor to obtain dynamic braking. With this

FIG. 2—GENERAL VIEW OF HOIST ROOM

The overspeed governor and limit switch are on the extreme right of the drum shaft. At overspeeds or overhoists in either direction this mechanism operates to stop the hoist automatically. A back-out switch permits the operator to operate the hoist again only in the safe direction after he has made an overhoist and been automatically stopped.

method, as the rotor is turned by the descending load, alternating-current power is generated by the rotor windings. When this power is absorbed in an external secondary resistance, true dynamic braking is obtained. Speed regulation is obtained by variation of the stator excitation and secondary resistance. This method of braking has not been used on mine-hoisting installations to any extent in the past, since on most installations the braking duty is not severe enough to warrant the extra complications and expense involved in the use of this system. Therefore the results which may be obtained by dynamic braking on induction motors are not generally so well understood as is the reverse torque method, which has been used with a great deal of success, particularly on small installations.

Final decision to install the dynamic braking control rather than the reverse torque control was made after a careful analysis of the two systems and was influenced largely by the material savings in power consumption and superior control obtainable with the dynamic braking system, for the difference in cost between the two was very slight.

Use of power while lowering with the dynamic braking system is limited to that necessary for the operation

FIG. 3—700-HP. WOUND ROTOR INDUCTION TYPE HOIST MOTOR

To facilitate inspection, cleaning and repair the motor stator may be easily moved to the side. A large flexible coupling connects the motor to the hoist.

of a small exciter, while with the reverse torque method practically as much power is taken from the line in lowering a given load as would be required to hoist the same load and a much larger resistor is required than is the case with the dynamic braking control used because the resistor must not only absorb the power generated by the descending load but must also absorb nearly all of the power taken from the line.

Superior control is possible with the dynamic braking system because of the possibility of adjusting both the stator excitation and the secondary resistance, thus obtaining a wide range of torques and lowering speeds. To obtain the same nicety of operation by the reverse torque method would require a controller with a large number of points.

The equipment finally decided upon and installed at the Packer No. 2 slope consists of a 700-hp. 500-r.p.m. 2,200-volt 3-phase wound-rotor motor geared to a hoist having a cylindrical drum 8 ft. in diameter and 6 ft. wide. Figs. 2 and 3 show the general appearance of the combined hoist unit as installed. The motor is

of the underslung type of construction with low pedestal bearings and includes provision for accurate movement of the stator for adjusting the air gap as well as for sliding the stator off the rotor for the purpose of inspecting or repairing either rotor or stator windings.

The motor is mounted on a bedplate continuous with the hoist bedplate and is connected to the hoist gearing through a flexible coupling. The hoist is equipped with cut steel herringbone gears with an enclosing gear case, a drum brake of the post type, a pinion shaft brake of the band type, an overspeed governor, and a geared limit switch. The brakes are of the gravity-applied, air-released type, air being furnished by a small motor-driven compressor. Emergency operation of the brakes from overtravel, overspeed or failure of power is taken care of by a magnet release device, failure of current on this device causing application of the brakes.

The control equipment consists of a primary circuit-breaker panel, air-break primary reversing contactors, excitation contactor, air-break secondary contactors, grid resistors, master controller, control circuit transformers, and exciter motor-generator set with its control equipment. The scheme of electrical connections and the sequence diagram are shown in Figs. 4 and 5. The appearance of the control equipment as installed is shown in Figs. 6 and 7.

The exciter motor-generator set consists of an 18-kw. 60-volt d.c. generator direct-connected to a 25-hp. a.c. motor, and operates at 1,800 r.p.m. The motor-generator set is operated from the same transformers used to supply current for the operating magnets of the contactors on the control panels. All contactors are magnetically operated with alternating current; no dynamic braking is obtained in case of power failure.

Several interesting problems arose in laying out the control equipment, particularly in regard to convenience of operation, reliability and safety. As finally designed

all operations are logical ones and do not call for unusual concentration on the part of the operator. Movement of the master controller from the "off" position, either hoisting or lowering, tends to give an increase of speed, while slow-down is obtained by an opposite movement. This is accomplished by a different sequence

of operation of the secondary contactors for the two cases.

A study of the curves, Fig. 8, shows that the lowest speeds with dynamic braking are obtained with the lowest resistance, while the reverse is true in hoisting. The design of the secondary resistance, particularly as regards the resistance values at the different control points, had to be a compromise between what would give best results for power and braking operations. Some of the points absolutely necessary for power operation were useless as braking points, and similarly it was necessary to provide braking points not needed for power points.

Reference to Figs. 4 and 5 will show that only four of the secondary contactors used for power operation are used in braking, while one secondary contactor used in braking is not used for power operation at all. Additional contactors for braking operation would have been necessary if advantage had not been taken of variation of the stator excitation to give additional control points. Separate current-limit relays were added

to the control equipment to take care of deceleration on the dynamic-braking connection, as it was desirable to use a different current setting for braking than was desirable for hoisting.

The relays on the braking connections serve a somewhat different purpose than those on the power connections in that their purpose is not to limit the decel-

FIG. 5—SEQUENCE TABLE SHOWING WHEN EACH CONTACTOR FUNCTIONS

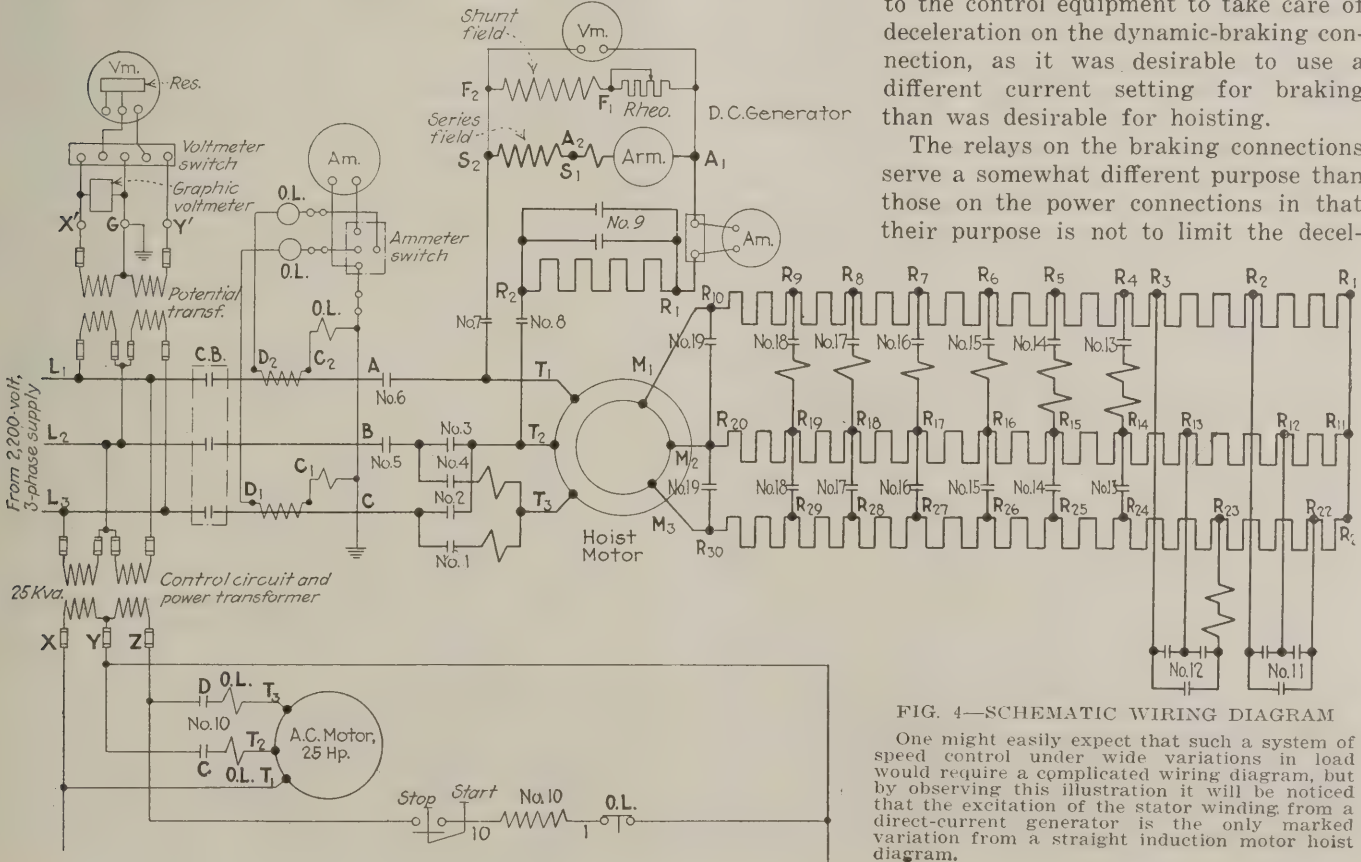

FIG. 4—SCHEMATIC WIRING DIAGRAM

One might easily expect that such a system of speed control under wide variations in load would require a complicated wiring diagram, but by observing this illustration it will be noticed that the excitation of the stator winding from a direct-current generator is the only marked variation from a straight induction motor hoist diagram.

FIG. 6—PRIMARY AND SECONDARY CONTACTORS

All the circuits are made and broken by means of heavy air-break contactors. The contactors in the foreground are the primary reversing switches.

FIG. 7—SECONDARY CONTACTOR PANEL

These switches control the hoisting speed and also assist in controlling the dynamic braking. On the left is the main-line oil switch supplying 2,300 volts to this hoist.

erating torque in any way, but rather to obtain such operation of the control equipment as to insure against loss of braking torque resulting through cutting out resistance too rapidly. Primary reversing contactors and power points in the lowering direction were incorporated into the controller to take care of the necessity of turning the hoist drum over for "slacking" cable. One point was added to the master controller for this purpose, this point being connected in series with a foot-operated switch so that, to get power in "lowering," the master controller must be left on this point and the foot switch operated. In normal operation this point on the master controller is passed over without any operation of the contactor panels.

The fact that this hoist has been giving unusually satisfactory service since it was put into operation, over two years ago, is the best evidence of good engineering in the selection of the equipment. The operations are simple, and do not tend to confuse the hoist operator. In hoisting, the controller is handled in much the same manner as the throttle lever on a steam hoist while in lowering speed control is obtained by the master controller in a manner very similar to that which the operator would use if he were handling his brake lever to lower against the friction of mechanical brakes, or his reverse lever to lower a load against the torque of a steam engine. Braking torques sufficient to control the heaviest loads without recourse to the mechanical brakes, except at very low speeds, are available, and the methods of control of braking torque provided are so flexible that the operator can lower at maximum speed with light or heavy load as the conditions may require.

The manner in which this equipment has been installed is in full accordance with the importance of the installation, and the successful operation of the equipment is in no small measure due to the care and consideration used in laying out the hoist and installing the equipment. The hoist house, shown in the headpiece, is a two-story brick building with two rooms on each floor. The hoist and driving motor are housed in a large room on the second floor while the small room on the second floor houses the circuit breaker, magnetic control panels, control transformers, exciter motor-generator set, and air compressor.

The space under the hoist room is pretty well filled

with foundations, but affords room for a small workshop and place for the storage of materials. The grid resistors are housed in a room directly under the contactor panels, thus affording short connections between the secondary contactors and the resistors. Ample ventilation is provided for the resistors by openings in the walls and a ventilating fan and chimney.

The arrangement of the apparatus on the operating platform of the hoist has been given a great deal of consideration and care. Control and brake operating mechanisms are within easy reach of the operator, as also are the operating panel for the main circuit breaker and the panel for the exciter. Closing of the main breaker puts the whole equipment in readiness for service since the air compressor and exciter motor-generator set are provided with automatic starters. Operation of the air-compressor unit is governed by the

FIG. 8—DYNAMIC BRAKING CURVES

Showing the widely different lowering speeds obtainable on different positions of the master controller. Notice how the speed-torque curves depend upon the direct current excitation of the stator winding.

air pressure. Air gages show operation of the air-braking system while electrical meters do the same for the electrical equipment.

The system used on this installation is well adapted for any type of unbalanced hoist where positive speed control is desired in both directions of operation, and where in normal operation power will only be required in one direction. Effective braking by electrical means is obtained down to very low speeds, reducing mechanical braking to a minimum. The system is not so well adapted to balanced hoists where occasional braking is desired, due to the fact that at times braking may be required in either direction, while at other times power may be required in either direction. However, this condition could be taken care of by the use of a separate reversing controller mechanically or electrically interlocked with the main master controller.

Advantages of Byproduct Coke For Domestic Heating

**Eliminates Smoke, Reduces Need to Clean
Furnace and Flues, Requires Less Attention
Than Coal and Gives Even Temperature**

BY A. R. POWELL*

The Koppers Company, Pittsburgh, Pa.

DURING the last decade the use of byproduct coke for domestic heating purposes has grown by leaps and bounds until at the present time it must be considered one of our staple fuels. The substitution of byproduct coke for raw coal has decreased the smoke nuisance in many of our cities, and it is not impossible to foresee a time when coke will entirely replace bituminous coal, in which event our smoke problem, with its consequent tax on the health and pocketbooks of city dwellers, will be a thing of the past.

In spite of the convincing evidence of the superiority of byproduct coke as compared to the majority of other fuels used for domestic heating, some misunderstanding regarding it still seems to exist. A statement has recently been made which might give the impression that "hard metallurgical coke" has not given satisfactory results when used as a domestic fuel. Without attempting to controvert the possible usefulness of any other type of fuel for domestic heating, we must not lose sight of the fact that coke of the "hard metallurgical" type is giving satisfactory service to thousands of domestic consumers and that the sale of coke for domestic purposes is increasing enormously.

For many years the U. S. Bureau of Mines has conducted experiments on the burning of coke and other fuels in house-heating furnaces. The following quotation is taken from Technical Paper 242, by Henry Kreisinger and A. C. Fieldner:

"Coke should be used for heating houses because it is a clean and convenient fuel. It eliminates smoke, reduces the necessity of cleaning the furnace and flues, requires less attention than coal, and gives a more uniform temperature in the house."

I have first-hand knowledge that at least some of the men who have had charge of fuel investigations for the Bureau of Mines now use byproduct coke of the "hard metallurgical" variety for the heating of their own

homes and these men assert that they will never return to any other fuel now used. If these investigators of many years' experience practice and preach the doctrine of byproduct coke, with no "axe to grind" in so doing, can we conclude that byproduct coke is unsatisfactory as a domestic fuel? The answer is obvious.

And if unprejudiced fuel experts prefer byproduct coke in their own homes, should not the average householder use that fuel also? Perhaps it requires an expert to operate on byproduct coke, and the average citizen would be unable for this reason to enjoy the benefits accruing from its use. The answer is found in a letter written by O. H. Prestemon, a citizen of Minneapolis, where the winters are long and cold and where the fuel problem is of vital importance to all householders. The following is quoted from this letter:

"The proof of the pudding is in the eating.' I have kept an accurate account of the monthly fuel consumption required to comfortably heat my seven-room home for three years. . . . My fuel bill is 15½ per cent less than when I used coal, in spite of increased prices. This is more convincing to me than laboratory tests.

"Besides lower cost, other advantages equally important are:

"Cleanliness.—The furnace is clean and free from soot, thereby increasing its heat radiating efficiency. The furnace room is clean and consequently you are not carrying coal dust on your shoes all over the house. From the point of view of the lady of the house this is important.

"Reduced Labor.—It cuts the trips to the furnace room to about two per day.

"Uniformity of Quality.—When you buy [byproduct] coke you know exactly what you are getting.

"Evenness of Heat.—The heat is steady and even, but easily regulated.

"Low Ash Content.—Perfect combustion reduces the ash nuisance to a minimum."

The experience of this householder must be multiplied many thousands of times to gain a true idea of the enormous quantities of byproduct coke now being successfully used for domestic heating. After all, this is the criterion by which the usefulness of any marketable article must be judged, and in view of the fact that byproduct coke of the "hard metallurgical" type has many thousands of enthusiastic users, we must conclude that it is a satisfactory domestic fuel.

Some consumers of byproduct coke have gained a misconception of its usefulness by improper methods of firing. Coke occupies more volume per given weight than coal and the fuel bed necessarily must be thicker. Also when the fire is once started very little draft is required in the case of coke. If these two rules are followed the fire will maintain a steady rate of heat generation for long periods of time. Clinkering results from the fuel bed getting too hot and any troubles of that kind when coke is used are due to leaving the draft open too wide, thereby getting an intensely hot fuel bed.

The burning out and bending of grate bars will be caused if ashes are allowed to accumulate in the pit, and this is true of coal as much as it is of coke. In fact, any fuel will give bad results if improperly fired. In the early days of anthracite a prejudice existed against its use because it "didn't burn easily." The rules for firing coke are just as simple as those for

*Industrial Fellow, Mellon Institute of Industrial Research.

firing coal; but they are somewhat different, and neglect to observe these will result in failure, as will be the case with any fuel if not properly fired.

In some ways it seems useless and foolish to justify the usefulness and practicability of a domestic fuel which has so thoroughly justified itself in many thousands of homes, and which, when subjected to scientifically conducted heating tests, has shown the highest furnace efficiency of any solid fuel on the market. Since some misunderstanding seems to exist, however, and since this may create a false impression, it is well to emphasize the well established position of byproduct coke as an ideal domestic fuel.

The following excerpts from Technical Paper 315 of the U. S. Bureau of Mines on "Comparative Tests of Byproduct Coke and Other Fuels for House-Heating Boilers," give some interesting data to the coke user:

"The first series of tests, 27 in all, was made in the fuels laboratory of the Pittsburgh experiment station with small steam boilers suitable for heating a seven or eight-room house. The fuels were byproduct coke, anthracite, and Pittsburgh coal. The second series, 17 tests, was made in the fuels laboratory—built for these tests—at the Minneapolis station of the Bureau of Mines, with a small steam boiler of similar size to that used in the tests at Pittsburgh, and with another larger boiler of the type used in heating small apartment-houses. The fuels used were byproduct coke, anthracite and Illinois coal.

"As far as possible, the boiler was operated as it would be in actually heating a house. A test usually lasted from Monday morning until Friday or Saturday morning; and at night the fuel was burned at lower rates than in the day time. A more detailed description of the method of operation will be found under 'Method of Conducting Tests.'

"A brief summary of the results is given in Table I, which shows that the efficiency was as high with byproduct coke as with anthracite. In fact, the two Capitol boilers gave somewhat higher efficiencies with coke than with anthracite. The efficiencies obtained with Pittsburgh and Illinois coal were 8 to 20 per cent lower than that obtained with byproduct coke.

"The relative quantities of bituminous coal, coke, and anthracite needed to maintain a house at a comfortable temperature during the winter depend upon the calorific values of the fuels as well as the thermal efficiencies; and the calorific values of all three fuels may vary considerably, owing principally to their variable ash and moisture content. The Pittsburgh tests showed that about 10 tons of Pittsburgh coal was equal to 9 tons of coke, or 8½ tons of anthracite when the fuels were burned in the Arco boiler; and to 10 tons of coke or 9 tons of anthracite when burned in the Dunning boiler.

"The Minneapolis tests showed that about 10 tons of Illinois coal was equal to 7½ tons of coke or anthracite when burned in the smaller Capitol Winchester boiler, and equal to 8½ tons of coke or anthracite when burned in the larger Capitol boiler.

"With the same attention to the fire, coke gives a much more uniform temperature than bituminous coal. In addition, coke is a clean fuel and makes neither smoke nor soot, an advantage difficult to express in exact figures. It is nearly as good a fuel as the domestic sizes of anthracite, and if anthracite is unavailable at reasonable prices a byproduct coke makes a good substitute.

TABLE I—EFFICIENCY OBTAINED WITH DIFFERENT FUELS WHEN THE BOILERS WERE ABSORBING HEAT AT RATE OF 2,500 B.T.U. PER SQUARE FOOT OF HEATING SURFACE PER HOUR.

Name of Boiler	Size		Thermal Efficiency. Heat Absorbed by Water in Boiler in Per Cent of Heat in Coal Fired			
	Heating Surface, Square Feet	Grate Area, Square Feet	By-product Coke	Anthracite Coal	Pittsburgh Coal	Illinois Coal
Arco, No. 6-23-S.....	39	2.9	70	70	54	..
Dunning, No. 303-S.....	46	3.6	70	70	62	..
Capitol Winchester, No. 3450...	33	3.3	70	69	..	49
Capitol, No. 257.....	106	8.6	66	60	..	50

"The quality of the fuels used in the Pittsburgh series of tests was as follows:

"The anthracite was taken from the bureau stock. It was a mixture of egg and nut sizes, and was considerably cleaner than that ordinarily obtained in the Pittsburgh market.

"The Pittsburgh coal was also a mixture of egg and nut sizes. It was purchased from a local coal dealer, and was of good average quality.

"The byproduct coke was furnished by the Carnegie Steel Co., and was made in that company's byproduct plant at Clairton, Pa. It was domestic-size coke, similar to nut-size anthracite, and was taken from a stock bin containing a mixture of 60 per cent 21-hour and 40 per cent 19-hour byproduct coke. The coal from which the coke was made was a mixture of several coals from the Klondike region near Pittsburgh.

"The anthracite and Illinois coal used in the Minneapolis tests were purchased from local coal dealers. They were a mixture of egg and nut sizes, and were of good average quality.

"The byproduct coke was purchased from the Minnesota Byproduct Co., St. Paul, Minn., and was made from Eastern coal. It was of domestic size, similar to the nut-size anthracite.

"None of the three fuels gave particular trouble with clinker. Although the coke clinkered considerably more than any of the other fuels, the clinker was light and porous. It formed a circular disk covering the central part of the grate, and if the fire was not too hot, the whole disk was easily removed in one piece through the firing door. With a hot fire, the clinker was soft and broke into small pieces when an attempt was made to remove it. For this reason, the best time to clean the fire is in the morning when the fire is cool after the night period of low rate of combustion.

"The Pittsburgh and Illinois coals made practically no clinker. However, to offset that, a heavy deposit of soot formed on the surface of the boiler. If good results are to be obtained, the soot should be swept off the boiler's surface frequently, preferably every morning.

Rules for Burning Coke.—A complete set of instructions on how to burn coke in house-heating equipment has been given in Technical Paper 242. The following rules contain the instructions in condensed form:

"(1) Carry a deep bed of fuel; one about 18 in. thick gives the best results.

"(2) Use very little draft after the fire is started, and keep it always under control. The success of even heating depends on careful draft regulation.

"(3) Do not stir the fuel bed; clean the fire in the morning.

"(4) Use sized coke: ½ to 2 in. for furnaces, boilers, and stoves; ½ to 4 in. for open grates.

"(5) Do not allow ash to accumulate in the ashpit."

What American Coal Mining May Learn From Europe's Mines

With Limited Coal Resources That Continent Is More Conservational Than America and Spends More Labor and Capital to Save Coal—Depth and Thin Beds Also Reduce Output—Great Care Expended to Protect Life—Wage Provisions in Great Britain and Excellent Housing on Continent Reduce Discontent

BY JOHN T. RYAN

President, Mine Safety Appliances Co., Pittsburgh, Pa.

ABOUT 90 per cent of the world's coal comes from two areas, relatively small when compared to the total surface of the earth. One of these embraces the coal fields of the eastern part of the United States, and the other includes the fields of Great Britain, Germany, Belgium and northern France. The European area supplies about 40 per cent of the world's coal and about 45 per cent comes from the coal fields of the United States. For the first half of the year 1923 the data collected by our Geological Survey show a total production for the world of approximately 660,000,000 metric tons of 2,205 lb. The United Kingdom of Great Britain produced 21.5 per cent of this total, Belgium 1.6 per cent, France 2.71 per cent, the United States' percentage of the total being 44.18.

To give an idea of how the relative production has changed we will go back to the year 1865, when Great Britain alone produced 100,000,000 tons, which was four-fifths of the world's output, and the United States supplied only approximately 20,000,000 tons, which was 16 per cent of the total world production. Great Britain's output increased steadily until 1913, when it reached its peak with a production of 287,000,000 tons. In 1922 it produced 249,000,000 tons, but in proportion to the world's production its output shrank steadily, being 80 per cent in 1865 and only 21 per cent in 1922.

It is interesting to note also the trend of the production per miner per year during recent years. The output per underground miner in the United States in 1901 was 651 gross tons, and in 1918 it was 1,012 tons, whereas the output per underground miner in Great Britain decreased from 357 tons in 1901 to 301 tons, in 1918. As there are many more workers on the surface at the mines of Great Britain than at those of the United States, if the comparison was made for all employees the difference would be greater. Thus the production per man per day involving all employees of

the British mines in 1922 was only 0.95 ton, and the production per man per day in Belgium and France is now only about 0.6 ton, whereas in the United States in 1922 it was approximately 3.6 tons for all employees.

There are many causes for this great difference in the productive capacity of the miner. One vital reason is the fact that nature has not been so good to the European countries as to us. Their coal outcrops are comparatively few compared with ours. Few valleys are so deeply eroded as to expose the coal seams whereas in western Pennsylvania and West Virginia such exposures are relatively common. Then again the coal has been mined in Europe for a much longer time. In fact there are authentic records that coal mining was practiced over 1,000 years ago, and at a point near Dunfermline, in the West Fife coal field of Scotland, the monks were mining coal as far back as the year 1291.

NO LONGER ARE OUTCROPPING SEAMS AVAILABLE

Naturally in the early years of mining in Europe coal miners followed the lines of least resistance, as we are doing in this country. They mined the seams nearest the surface, of the greatest thickness and the best quality without proper regard to the possibility of removing later the seams above and below. I would estimate that 90 per cent of the coal production in Great Britain comes from shaft mines from a few hundred feet to 3,500 ft. in depth and about 95 per cent of the production of Belgium and France comes from shaft mines.

Many of the mines in these latter countries descend to a depth of over 3,000 ft. and several are now being sunk which will go to a depth of 4,000 ft. In France and Belgium seams of coal are being worked as thin as 15 in. and some of these are at considerable depth. Few of the seams in their present coal fields are over 3 ft. thick. Practically all of the mining in these countries is by longwall.

In Great Britain there are fourteen separate coal fields. The thickness of the coal varies considerably in thickness, as does the number of workable seams. In the North Staffordshire field, as an illustration, there

Article entitled "Some Observations on Mining in Europe" read before the Coal Mining Institute of America, Dec. 19, 1923, at the annual session held at the U. S. Bureau of Mines, Pittsburgh, Pa.

The illustration in the title shows one of the many girls on the tipples of Scotland. Mr. Ryan says that this is one of the reasons why Sandy hates to leave his native heather. When Parliament, before the war, threatened to dispossess the girls of their jobs they sent a delegation of protest to London, and Parliament relented.

MINE NO. 11, LENS COMPANY, UNDER RECONSTRUCTION

This mine had been running twenty-five years when it was destroyed by the Germans. It is expected to be active for another 100 years.

are about thirty seams of coal having a thickness of 2 ft. or over, making a total thickness of 140 ft. A number of other seams range from 1 ft. to 2 ft. in thickness, making a total of 150 ft. of available coal. Many of the shafts from which they are now hoisting coal have been in operation for several hundred years. For instance one, at least, in the town of Newcastle-on-Tyne has been in operation for over 200 years.

Many of these old shafts were sunk originally to one of the thicker beds near the surface and after they were exhausted they were deepened to tap lower seams. In some of the shafts six or seven different seams are being worked. These old shafts were rather small, usually accommodating cars having a track gage of only 20 to 22 in. The cars, or "tubs," held about 800 lb. As these standards have continued with the deeper shaft workings and as the distances from the shaft have increased, one can readily form an idea as to the way in which these narrow gages and small cars reduce production.

TROLLEY WIRES EXCLUDED FROM BRITISH MINES

Another vital fact which affects production is the almost entire exclusion of electricity from underground workings. It is excluded absolutely for haulage purposes, as the British regulations state "Haulage by electric locomotives of the overhead trolley-wire system is prohibited in any of the coal mines." The same regulations are in effect in Belgium and France. This means that all their transportation is by rope, horses and man power, for, indeed, there is much of the latter at the working faces.

Labor-saving machinery is used comparatively little in the European areas described. Whereas about 65 per cent of the coal of the United States is mined by machinery, only about 15 per cent of the European coal is mined in that manner.

Two other factors that I think enter to a great extent in the decreasing production rate of Great Britain are the introduction of the seven-hour day from bank to bank, which means that the face worker works only five and one-half to six hours. The other is the fact that our miner here actually works harder and is much happier and more contented than the British miner. I do not believe, however, that our miners work any harder than the French and Belgian miners or are any more contented. Reference to the reasons for this statement will be made later.

Our American mining men will find little in European

production and mining methods of interest to them, for few of the practices in these mines can be applied to the conditions in the United States, unless, indeed, the mine operator is an optimist and expects to live 500 years longer. It will be approximately that length of time before we will be mining under physical conditions comparable with those faced at present in the coal fields of Europe.

Another condition which must be taken into consideration also is that in Europe the coal resources are not, as in America, almost unlimited, for with the average production in Great Britain of 250,000,000 tons per year the British will exhaust their present probable coal resources in 744 years, whereas the United States, at an average rate of production of 600,000,000 tons per year, will not complete the mining of its coal for 7,677 years.

Consequently in Europe they are obliged to pay more regard to the economic value of the coal in the ground and to the conservation of their coal resources. Taking these facts into account as well as the unfavorable natural conditions for mining as compared with our own, their engineers are doing a good job in the mining of their coal.

There are several phases of European mining, however, that American mining men would do well to study, for their effects will be reflected on this side of the Atlantic, and regarding these I desire to say something. Though our mining and production methods are not comparable, the question of "What's in the worker's mind" and how to keep the miner and his family contented is not dissimilar in the two great mining regions. The problems of education, living conditions, recreation and wages are matters which are important and comparable, and hence worthy of our consideration.

UNIFORM LAWS IN ENGLAND, SCOTLAND AND WALES

Then there is the big question of safety, and from the experiences, practices and mining legislation of the European countries we can learn much. Practically everything pertaining to safety in Great Britain is covered by regulations dating back to 1872, and revised from time to time to bring them up to date. The regulations are uniform for all the mining districts of England, Scotland and Wales, which is a great advantage from the standpoint of safety.

In addition to the Coal Mines Act, which was codified and modernized in 1911, the Secretary of State may by order make such general regulations as may appear best

WINTERSLAG COLLIERY, NORTHEASTERN BELGIUM

A mine in a new field. It employs 5,500 men, about 4,000 being underground workers. The output per day is about 2,300 tons.

calculated to provide for the safety, health, convenience and proper discipline of the persons employed in and about the mines. This provision of the act has enabled the Mines Department to put into effect in recent years a number of general regulations pertaining more particularly to rescue work, safety lamps, use of explosives, coal-dust explosion hazards and the like.

For convenience, the fourteen separate coal fields are divided into six separate divisions by the Mines Department. The staff of inspectors in addition to the chief and deputy chief, consists of six divisional inspectors, fourteen senior inspectors, thirty-two junior inspectors, twenty-one sub-inspectors, eight quarry inspectors and eight horse inspectors. Each of the six divisions has a divisional inspector, from one to four senior inspectors and from two to six junior inspectors, and sub-inspectors depending upon the size of the division. The rates of pay and cost of living bonus are as follows:

Divisional inspector	\$5,000 to \$6,250
Senior inspector	3,850 to 5,000
Junior inspector	2,500 to 3,500

The inspection department is made up of high-grade, well-paid, efficient men, and the department has the necessary power to enforce uniform regulations. The average rate of pay to the British miner is only one-half to one-third of our miner's pay, whereas the salary of the inspector is about double the average received by our inspectors. This comparison is a great discredit to the United States, and our mining men should take steps to increase the salaries of our mine inspectors, paying them more nearly what they are worth, and building up the departments for an even better inspection service in the future. We should also take steps to bring about more uniform regulations in all our coal-mining states.

The Belgian and French regulations are, if anything, more severe than in Great Britain. In France the government holds title to all the coal land and leases it by grants or concessions, and the safety of the mines is under the control of the government inspection corps, which has the power to make and enforce regulations. It is a well-paid, highly efficient body of men, and that fact is reflected in the excellent accident record of the mines it supervises. The death rate from accidents in and about the mines in Great Britain per 1,000 persons employed has dropped from 2.24 in the year 1873 to 0.95, or less than one, in 1922. The death rate for each million tons of coal raised decreased from 7.42 in 1873 to 4.32 in 1922.

Statistics for the United States in the same period show that in 1873 the number killed per 1,000 was 5.46 and the number killed per million net tons mined was 10.06. In 1922 the number killed per thousand employed was 2.3, and the number killed per million net tons mined was 4.3.

WHY FALLS CAUSE LARGE PART OF ACCIDENTS

In analyzing and comparing the causes of accidents, we find that in Great Britain in 1922, falls of roof were responsible for 55 per cent of all the underground accidents, and haulage accidents for 21 per cent. In the coal fields of the north of France for 1922, falls accounted for 71 per cent of all underground accidents and haulage for 14 per cent.

In the large coal fields of the north of France, producing about two-thirds of France's total output, it is interesting to note that the death rate in 1922 was only

PLANT OF LENS COMPANY NOW NO LONGER IN RUINS

The plant which preceded this was destroyed only a few days before the armistice, but it had been under fire for no less than four years. Order and permanence are distinguishing features of European mines.

one per two thousand men employed, and there was not a fatality from either gas or coal-dust explosion. Yet this in a field in which all the mines are gaseous, very deep and dry. This field, employing 100,000 men, has not had a gas explosion since 1917.

The statistics for both of these countries show that the larger percentage of accidents occurs from falls—even a greater percentage than in the United States, for in 1922 only 50 per cent of our underground fatalities were from this cause. The reason for this higher percentage in the European countries named is that the roof they have to control is much worse. They have cut down fatalities from other causes to a greater extent than we have, and in consequence the percentage of accidents from falls and haulage accidents looms higher than it would otherwise.

In France centralized rescue stations have been erected to serve all mines, but the regulations also require that each mine must have on hand two sets of apparatus. The French had a fine central rescue station at Bruay, in the northern field, before the war, but it was completely destroyed by the Germans. However, they are now just completing a magnificent central station near by Bruay but on the outskirts of the city of Lens. This would cost, if duplicated in this country, about \$300,000.

The wage problem and method of determining the wage scale is an interesting phase of European coal mining, and particularly in Great Britain. It is so badly complicated there that it almost takes an accountant to figure it out. I will endeavor to give you briefly the operation of the national wage agreement as contained in the annual report of the Secretary of Mines of Great Britain for 1922:

"The object of the agreement is to provide machinery by which wages may from time to time be automatically adjusted in accordance with the selling price of coal. Its purpose is that the proceeds available for wages and profits (i.e., the gross proceeds less costs other than wage costs), commonly known as the 'net proceeds,' shall be shared in an agreed proportion which works out at about 85 to 15, or, in other words, of every £100 available, wages are to have about £85 and profits about £15.

"For instance, if the 'net proceeds' per ton are 12s.6d., wages are to be paid at such a level as will make the wages cost per ton 10s. 8d., leaving 1s. 10d. profit; if they are 15s. the proportions will be 12s. 9d. and 2s. 3d.;

BICYCLE GARAGE AT WINTERSLAG COLLIERY

About 4,000 bicycles can be stored in this building. In Europe miners ride to work on bicycles instead of in Fords.

if 17s. 6d., they will be 14s. 11d. and 2s. 7d.; if 20s., they will be 17s. and 3s., and so on.

"This is to be secured by determining the actual amount of the 'net proceeds' during a period of two months and fixing a percentage to be added to basic wage rates during a future two-month period, at such a level that wages will absorb, during that period, a sum equal to the agreed proportion of the amount of the 'net proceeds' during the past period.

WAGES MUST NOT FALL BELOW FIXED LEVEL

"This process is, however, subject to one important qualification: That the miners' rate of wages per shift must never fall below a certain specified level. If 85 per cent of the 'net proceeds' shown by any ascertainment is insufficient to pay wages at this guaranteed level, the 15 per cent must be encroached upon or foregone altogether, or even a sum greater than the whole amount of the 'net proceeds' must, if necessary, be provided. When the agreed share applicable to profits is thus diminished, the owners are entitled, according to the actual terms of the Agreement, to recoup themselves in certain circumstances for some part of these overpayments, but in all ordinary circumstances this provision, for reasons which it is unnecessary to examine here, will be inoperative, and the owners in fact must write off their losses at once.

"In theory, of course, this principle might be applied to any unit, from the single mine at the one end of the scale to the whole of the British coal fields at the other. In practice, the unit is the 'district'; that is to say, a number of mines geographically adjacent to one another, the natural conditions of which are similar. Great Britain is divided into thirteen such districts.

At the base of this national agreement is also a minimum-wage provision which guarantees the men a minimum daily wage which at the present time is approximately, for the average of all the districts, 9s. per day, and this is arrived at in the following manner: Before the war the average daily wage of the miner was approximately 4s., or \$1. During the war the base rate was increased 50 per cent, or from 4s. to 6s. In 1919, when the working day was decreased from eight to seven hours, the pieceworkers were awarded an increase of 14.2 per cent for the loss of this one hour, but this did not include the daymen. This was known as the Sankey Award. After the strike of 1921, which brought about the national wage agreement on the profit-sharing basis, the base rate was increased an additional 28 per cent, making it now approximately 9s., or \$2.07.

The average wage of the 1,129,539 men employed for 1922, working an average of 251 days a year, was 9s. 11½d. per day, or \$2.29 in our money today.

In addition to the provisions of the national wage agreement and the minimum wage there is an unemployment wage, or "dole," which is paid by the government.

BIGGEST PAY IS \$1.33 PER DAY

In France the wage scale is based on the average pre-war wage plus a percentage equivalent to the increased cost of living as compared with the pre-war cost, subject to variations due to the number of dependents. The French mines have been practically free of wage controversy since the war, but in November of last year they had a suspension of a few days' duration, as the men asserted that the wages had not been adjusted to take care of recent increased costs of living. This controversy was settled by granting an increase varying from 1 to 3 fr., which in our money would be 5c. to 15c.

The average wage for men working at the face, prior to this last advance, was 25 fr. per day or the equivalent of \$1.33 in our money.* The average for outside work was 17 fr. (\$0.90) per day, and the majority of this outside work is done by girls. The average for all men and boys about the mines is 17 fr. (\$0.90) per day. Children from 13 to 15 years of age made from 2 to 5 fr. (10c. to 26c.) per day. The 8-hour day is in general operation.

A study of how the miner lives, what he does above ground, what provisions are made for the comfort and welfare of the family in these European countries will

*Figured at 5.32c. per franc. It is now just about 5c.

EARNINGS OF MINERS IN THE SEVERAL DISTRICTS OF GREAT BRITAIN

District	Average Earnings Per Manshift (All Classes)		Period During Which District Was on the "Minimum"	Average Number of Shifts Worked Per Year	Average Earnings Per Man Per Year		Average Output Per Man Per Year	
	s.	d.			£	s. d.

Average for all districts	9	11½	2.43		251	125 2 0	609.24	226

This table is based on normal exchange, \$4.87 per pound sterling. The present rate is \$4.34, or 11 per cent less.

be of interest. Great Britain has been backward along these lines, particularly in the way of proper housing, recreation facilities and miners' baths, etc., but recently steps have been taken to correct this by the Miners' Welfare Fund, established under the Mining Industry Act of 1920, "for the purpose of improving the essential wellbeing, recreation and conditions of living of the workers in, or above, the coal mines and for mining education and research." This fund is maintained by a levy upon all collieries of 2c. per ton of output over a period of five and one-half years. This levy will create a fund of approximately \$5,000,000 per year.

Bathhouses, or washhouses, as we term them, are practically unknown in Great Britain and only a handful of collieries are equipped with them and then only partly so. When you go across the channel to Belgium and France and visit their mines one of the first things to strike your eye is their magnificent bathhouses, the construction of which is required by law.

Due largely to the thin seams, the great depth at which they are found and the severity with which they are faulted, coal can be mined in France only by the exercise of unusual engineering talent. Perhaps for this reason all the officials down to the sub-foreman must have technical training. They do their mining work well and take excellent care of the safety of their men, but what excites most interest in the visitor is the manner in which they take care of the miner and his family on the surface. Fine homes with large gardens have been provided. Good playgrounds, unrivaled recreation facilities and good schools make life happy for the children. Some of the houses just constructed in the devastated area are equipped with running water and electric lights and are provided with a large plot of ground. Double houses of ten rooms cost 50,000 fr., which would represent in our money today about \$2,700. They rent for 10 to 15 fr. per month, or from 55c. to 85c.

One naturally wonders how with the working conditions worse than in Great Britain, on account of the low seams, the French operators can run their mines with a much lower wage scale and yet have far fewer labor disturbances and keep their men better satisfied. I believe the biggest factor in promoting this condition is the manner in which the operator takes care of the miner and his family on the surface.

A word about the devastation of the French coal mines by the Germans. The coal basin located in the northern part of France spreads over a large part of

NEW MINER'S HOUSE AT LENS, FRANCE.

The French companies are rebuilding homes at a rate of 5,000 a year, replacing those destroyed by the Germans.

two departments, or counties, the Nord and the Pas de Calais. This basin is an extension of the Belgian coal field. It extends practically across northern France, and its width ranges from ten to twenty-five miles.

Here also is the industrial center of France. It was invaded by the Germans, Aug. 24, 1914, their lines extending to the vicinity of Lens and Béthune. They captured about 80 per cent of the mines. The battle lines of this particular section varied but a few miles from 1914 to 1918. When the invasion took place it was so rapid that little destruction was done, and the mines captured were practically unaffected. In consequence the Germans were able to work them continuously until about Nov. 1, 1918.

TWO HUNDRED AND TWENTY SHAFTS RECONSTRUCTED

When they started to retreat and knew they were defeated and would not come back, they wilfully destroyed a total of 124 pits having 220 shafts. One hundred and forty of the shafts were dynamited. Practically all the surface plants were entirely destroyed. Out of a total of 30,000 miners' houses in the area, 16,000 were totally destroyed and most of the remainder badly damaged. The Germans occupied and worked these mines during the entire war but, though when they gutted the French mines they completely destroyed them, they left the Belgian mines practically intact.

The French have done wonderful work in the reconstruction of their mines and their mining towns, and they will complete this reconstruction work several years earlier than the best engineers estimated it could be done. It has been a remarkable accomplishment, and it is no wonder that the French who have had to provide the money for this re-establishment of the industry feel keenly the necessity for collecting reparations from the Germans.

CITÉ IN LENS REPLACING VILLAGE GERMANS BURNED

House construction at European mines is no more a source of profit to European operators than the houses in American towns are to the operators of America.

LIQUID OXYGEN THOUGHT DANGEROUS IN COAL MINES.—Liquid oxygen explosives are being extensively used in France and Germany in metal mining and quarrying operations, according to George S. Rice, of the U. S. Bureau of Mines, who recently returned from a trip to Europe. This type of explosive is not, however, being employed in coal mines because of the assumed danger of causing coal dust explosions. Tests employing liquid-oxygen explosives in quarries and metal mines in the United States are now being made by the Bureau of Mines at Pittsburgh, Pa., and at other field stations, Congress having at the last session, appropriated funds for the work.

The Miner's Torch

Giving Thought to the Under Dog

NOT long ago a friend of mine who is superintendent at a large coal-mine operation said to me in conversation that he wished he could find some bosses who would show enough interest in the company that employed them to fight for it if necessary; he said it earnestly, indicating that he had been giving the matter much thought. By way of continuing the conversation I asked him if he had ever had any men in his employ for whom he had been tempted to wage fight with his superiors to get for these men all that he thought was coming to them, or had he ever even mentioned any of these men to his superiors. His answer was not very satisfactory nor has his manner toward me been very cordial since.

A few days later I saw an article in a political monthly indicating that the labor legislation next proposed would endeavor to make a workingman's job something that could be depended upon in fair weather and foul. The argument for such a measure was something like this: Property rights are guaranteed to owners under our laws, and without such guarantees property would have little value. Certainly a laboring man's job is just as important to him and his family as property is to a land-owning farmer and his family, and it is just as reasonable to protect one by law as it is the other. I cut out the article, affixed my initials and mailed it without comment to my friend the superintendent, and as yet he has not acknowledged it.

I happen to know that this man has inaugurated an employment system that requires from each applicant for employment almost a life history, a doctor's examination, and a file of testimonials or references that are of equivalent value. He takes no chances at getting into his employ men who are likely to be injured because of inherited or previously acquired physical infirmities and in this way he keeps down to a minimum the payments required by the Workingmen's Compensation Act. If any of his employees lose a leg or an arm or an eye he tries to arrange a settlement with them that will be truly a final settlement so that they will seek employment elsewhere. He has stated publicly time and time again that he has a perfect horror of seeing cripples around his operations.

There is nothing peculiar or unusual about my friend's viewpoint on the accident question. Every superintendent who has been connected with mining operations for a number of years can recall times when it looked as if his company must surely become a bankrupt because of damage suits won or pending, and to such the merest mention of the words "claim for damages" is sufficient to produce a spell of "nerves."

But—every man feels that he has a right to earn a living, be he lame, halt or blind and unless more of our higher-ups forget the extremes of the past, when the ambulance chasers were in the saddle, and pay more attention to the extremes being inaugurated by the employment departments of the present day, the employees who are willing to fight for the employers will entirely disappear from the face of the earth and the labor problem will be a sure-enough problem. If you think

I am unduly worked up over this matter get your employment manager to show you his files of employment applications with all of the pertinent correspondence attached and note the comments added on the margins, then try to place yourself in the position of the men whose names are signed to the application.

Or, better yet, just drop in on your employment manager occasionally and listen in on the conversations between the applicants and the questioners, also the comments being made about rejected applicants when there are no applicants in the office and your "help" is in reminiscent mood.

For Flame Safety Lamps, Which Is Best: Flat or Round Wick?

BY J. W. PAUL

Chief of Coal Mine Investigations, U. S. Bureau of Mines,
Pittsburgh, Pa.

For a given percentage of gas the height of the gas cap in any lamp depends upon the temperature of the testing flame and the draught of the lamp. The hotter the flame the longer will be the cap. By special construction the cap may be elongated, and this may be accomplished by surrounding the flame with a small cylinder, usually of glass, which prevents loss of heat by convection or radiation. However, with the low percentage of gas, from 1 to 2 per cent, the heat evolved by the testing flame and the gas cap is not sufficient to increase materially the gas cap over that which is obtained with the ordinary lamp unequipped with the special chimney.

In determining the height of gas caps the reduced flame of the lamp is used, and this testing flame is approximately 0.1 in. high measured from the top of the wick holder. All gas-cap flames should be measured from the top of the wick holder as the line of demarcation between the test flame and the gas cap becomes lost after passing 2 per cent of gas.

Up to that percentage there is little difference in the length of the gas cap as shown in lamps used for general purposes, and in 2-per cent gas the round and flat wick lamps of the same design give the same gas cap; in 2½-per cent gas the round wick of one make of lamp gives a gas cap 0.05 in. larger than the flat wick and above 3 per cent the flat wick gives the higher cap.

The Bureau of Mines will soon have ready for distribution a bulletin on the miners' flame safety lamp in which elaborate data will be given on gas caps, also a number of charts giving a reproduction of the appearance of gas caps in different types of safety lamps.

The gas caps in the approved types of lamps have definite heights for each lamp, but the differences for low percentages are very slight, as may be observed from the following statement of gas caps:

With 1 per cent of gas the gas cap ranges from 0.15 in. to 0.3 in.; 2 per cent gas, 0.4 in. to 0.5 in.; 3 per cent gas, 0.6 in. to 0.9 in.; 3.5 per cent gas, 0.9 in. for round wick to 1.7 in. for flat wick; 4 per cent gas, 1.3 in. for round wick to over 1.7 in. for flat wick. With 4 per cent gas, the gas cap on all the approved lamps, except one round wick type goes above the top of the glass globe, and by interpolation the particular round wick cap reaches the top of the glass globe with 4½ per cent of gas.

Discussion presented Dec. 19 at the meeting of the Coal Mining Institute of America in Pittsburgh, Pa.

Sees Revolutionary Era Just Ahead Of Coal Industry

Impressed with High Order of Intelligence of British Coal Men, *Coal Age* Correspondent Stresses Mutual Advantage of Exchange of Experience with Mining Leaders in This Country

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

THE coal industry in South Wales has profited greatly by the employment of private cars for the transportation of its product. Now that the railroads in England have been grouped, there is some agitation on the part of the carriers for the pooling of cars or for the absolute change to a system car basis. This is opposed by most mine operators. The British law provides that the railroad must supply side-track facilities sufficient to take care of all cars offered. This is a great asset to the producers as they can hold their own cars under load as long as they wish without demurrage. It allows great flexibility in being prepared for any sudden demand such as the simultaneous arrival of a number of ships. In the north of England the cars are largely railroad owned as in America.

There are other reasons, in addition to the desire to do away with private cars, why the consolidation of railroads is not popular among the Welsh coal operators. Before the grouping each of the separate lines was anxious to offer some inducement to obtain business. Now with one system the railroad is much less obliging, it is asserted.

The Great Western R.R., which has absorbed the other lines in southwestern England and in south Wales, is taking an active interest, however, in stimulating the demand for Welsh anthracite. The railroad is more interested in expanding the domestic market for that fuel, which the British have not learned to use extensively, than it is in promoting export trade, because the former trade has for it greater tonnage possibilities. The road, however, is anxious to encourage exports as well, as a larger volume of production would reduce costs.

SUPERIORITY CLAIMED FOR WELSH ANTHRACITE

Officials of the Great Western were much pleased when American orders were placed for Welsh anthracite prior to our anthracite strike, as the wide publicity given the fact that Americans were sufficiently desirous of obtaining that coal to pay for its transport across the Atlantic had a psychological effect on the people of England. Thought is being given a plan whereby the Great Western and the Welsh anthracite owners may join in an effort to popularize the use of anthracite in Great Britain. A slight superiority over our anthracite is claimed for the Welsh product.

One of the outstanding things which impressed me in my contacts with the British coal industry is the high order of intelligence among the men who conduct it. The brain power of the industry is not confined to the principal executives. It is much in evidence all the way down the line, even to the subordinate grades of employees. It seems to me that it is a mistake not to have closer relationships between the men engaged in the coal business in the two great coal-producing nations. One of the lessons of the war has been that it is difficult for

one nation to be prosperous unless its neighbors also are prosperous. Great Britain, for instance, has learned that its own prosperity depends to a great extent upon the prosperity of Germany. Many of our own industries have suffered severely, and all of them have been hurt to some extent, by lack of prosperity in Europe. It is particularly the case that anything which contributes to the prosperity of Great Britain contributes directly to our own prosperity. Since coal is the basis on which British trade is built, the United States would suffer were that industry to languish. At any rate, there always should be co-operation in the exchange of experience and in developments which promote efficiency in the industry as a whole.

INDUSTRIAL TREND CALLS FOR CLEAR THINKING

The coal industry is on the threshold of an era of revolution. The advent of the internal-combustion engine, the increasing demand for the byproducts of coal and the burning of coal in large central power plants with the distribution of the resulting power as electricity, are examples of trends already exercising far-reaching effects. If the coal industry is to keep step with world progress and with progress in other industries, all of its brain power should be co-ordinated. A long step in that direction has been taken by the recent agreement between the governments of the United States and of Great Britain correlating their mining research.

Much constructive work could be done were machinery set up for the systematic consideration of problems common to the British and American industries. But lacking that, I believe there would be actual profit to the average American coal operator and to the average British operator in paying occasional visits to the other country. My experience with the British operators leads me to think they would take the broad view of any exchange of helpful information. An occasional one might take the position that a competitor—just at this time he might have to say "potential competitor"—should not be given the advantage of British experience, but that view would be held by very few.

BRITISH COAL INDUSTRY CAN LEARN FROM AMERICA

While there is much the American industry can learn to its advantage in British coal mines, there is also much the British can learn here. Now that the British are confronted with the absolute necessity of pulling up their low output per man and have turned definitely to a mechanical program in underground workings, one way in which they could benefit materially would be by visiting those mines in this country which now are so thoroughly equipped in a mechanical way.

This is the concluding article in the series written by Mr. Wooton as the result of his observation of the British coal industry.

New Western Maryland Ry. Coal Pier Is Electrically Operated

UTILIZING the site and foundations of the original gravity pier of the company, which was built in 1904 and destroyed by fire in September, 1919, the Western Maryland Ry. has constructed a new coal pier at Port Covington, Baltimore, that is operated by electricity. The original pier was of the timber trestle type, with forty coal pockets—twenty on each side—through which coal was transferred directly from cars to ships by gravity. This pier was 60 ft. high and 1,200 ft. long, extending 729 ft. out from the shore on timber piles.

The equipment of the new pier consists of a stationary car dumper of the lift and turnover type, with mechanical trimming apparatus for loading boats directly from the dumper pan, and an auxiliary conveying system and trimming apparatus to permit the loading of boats on the side of the pier opposite that on which the dumper pan is located. All of the pier equipment is electrically driven by direct-current motors, power being supplied at 230 volts from a 1,500-kw. rotary converter substation located on the pier.

CAR OVERTURNED WHEN DUMPING

As soon as the loaded car has been properly stopped on the cradle the operation of the cradle hoist is started. The starting of the hoist automatically shoves the car, which is now resting on a platen mounted on rollers, over to the side of the cradle and clamps it securely in the cradle, after which the cradle starts on its upward trip. When near the upper limit of travel the cradle strikes a turning pin and starts overturning, continuing until the car has been turned through approximately 150 deg., and spilling the coal onto a pan, which in turn empties into a chute reaching into the hold of the vessel being loaded. The illustration shows the dumper with a car completely overturned in the dumping position, and with the end of the loading chute in the hold of a vessel.

The dumper is designed to handle 100-ton capacity cars, although at the present time 50-ton capacity cars are being used. It is estimated that the maximum amount of coal that can be handled with 50-ton capacity cars per day (two 10-hour shifts) is 25,000 to 30,000 tons; with 100-ton capacity cars this would be increased to 40,000 to 50,000 tons per day.

VIEW OF PIER AND INCLINE

The electrical drive operates the turnover dumper, which turns the car through 150 deg., thus delivering the coal into a chute that carries it directly into the hold of the vessel.

As an auxiliary to the car dumper, the pier is equipped with a conveying system, a small storage bin and an auxiliary chute and trimming device. This auxiliary equipment permits the bunkering or loading of a vessel on the side of the pier opposite that on which the dumper is located. To put this auxiliary equipment into service, the hopper forming part of the main dumper pan is designed with a movable bottom plate in such a way that when this plate is hoisted the neck of the hopper connecting with the loading chute is cut off and the coal delivered directly into the vessel.

The control of the two barney haul motors is accomplished by means of two full magnetic type controllers designed to control the operation of the two motors in multiple from a single master controller. This controller is of the plain reversing type with armature shunt points provided for slow-speed operation. The principal feature in connection with the barney haul-control equipment is the method used for interlocking with the barney gate-control equipment and the methods provided for automatic slowdown. This is accomplished by the use of geared limit switches of the traveling nut type. The barney gate mechanism also is provided with a limit switch of the same type, and the scheme is worked out so that it is impossible to move the barney before entering the track gates unless these gates are in the correct position. The same switch also gives slowdown when approaching the upper limit of travel. The equipment was designed and manufactured by the Westinghouse Electric & Manufacturing Co., Pittsburgh, Pa.

THE WADGE and the Wolf Creek coal beds of the middle group in the Twentymile Park district of Colorado, according to a Bulletin 748 of the U. S. Geological Survey, are remarkably regular in thickness and distribution, ranging in thickness from 5 to 20 ft., and the beds in the lower group are remarkably irregular in both thickness and distribution. On Oak Creek the Pinnacle coal bed probably is the most valuable bed of the group, and persistent efforts have been made to show that this bed is the one worked on Yampa River near the mouth of Indian Creek. However, the thick coal beds on Oak Creek break up and diminish in thickness toward the west, and coal bed No. 3, which overlies the Pinnacle, is the only valuable one in Dunkley Canyon. Hence, the Pinnacle bed probably is not present at the mouth of Indian Creek, the beds mined there being members of No. 3 on Oak Creek, which here has expanded into a group.

USE OF ROCK DUST OBLIGATORY IN EUROPE.—In Great Britain and France, says George S. Rice on his return from a trip to Europe in behalf of the U. S. Bureau of Mines, the employment of rock dust as a screen or barrier for the limitation of coal-dust explosions to the immediate area of the explosion has been made compulsory. The efficacy of this method was strikingly demonstrated in the case of a gas explosion in a Yorkshire colliery, where the stone dusting confined the explosion to its immediate place of origin and prevented the great loss of life that must have occurred had the explosion spread through the mine. Much experimental work along this line has been performed in the United States by the Bureau of Mines, but the states have as yet enacted no legislation to compel the adoption of this system in the mines of the country.

News Of the Industry

Work Rejects Retailers' Plea to Abolish Government Fuel Yard

Secretary of Interior Says Retailers' Proposal Would Cause Loss of 37.6-49.5c. per Ton to Taxpayer—Suggests Restudy and New Proposal—Cost Compilations Differ

The taxpayer would suffer, says Dr. Hubert Work, Secretary of the Interior, were the government to accept the proposal of the National Retail Coal Merchants' Association to abolish the Government Fuel Yard and turn over the business of supplying the departments with coal to the Washington retailers. "Upon analysis of the proposals and of the figures taken from the records of the fuel yards," says Secretary Work in denying the plea of the retailers, "it appears that acceptance would result in the net loss to the taxpayer of 37.6 to 49.5c. per ton."

Secretary Work also makes the point that the retailers' proposal fails to give any satisfactory guarantee that any losses incurred by the retailers in handling the government's business would not be made up by additional charges against private consumers in the District of Columbia. In his communication, however, the Secretary resubmits this question: "At what margin per ton above mine cost and freight are the merchants prepared to sell coal of the various grades in the district?" To this Secretary Work adds: "It is possible that, on restudy of the matter, you may be able to propose a scale of margins that will permit the government to turn over to the local merchants the handling of all of its coal business in the District of Columbia."

Another point made by the Secretary of the Interior is as follows: "The taking over by the local merchants of the

unloading, trucking and delivery of coal to the curb, as proposed, would not relieve the government of the cost of purchasing the coal, making payment to mines and railroads, collecting from the departments, auditing accounts, weighing and inspecting all coal as provided by statute, arranging for and inspecting stowage, demurrage and loss, if any, between mine weights and delivered weights, interest on capital used in performing these functions and amortization of the investment in the present plant (less salvage) or cost of holding the yard in standby condition in the future. All these items have been urged by you as entering into the true cost of handling coal, as indeed they do."

In his reply to the retailers, Secretary Work submitted the accompanying comparison of present Fuel Yard costs with those which would prevail under the terms of the dealers' proposal.

With his reply Secretary Work made public the brief submitted in this connection by the National Retail Coal Merchants' Association. At the request of Secretary Work, this brief has heretofore been withheld from publication.

In a letter accompanying the brief of the retailers Roderick Stephens, chairman of the Government Relations Committee of the merchants' association, reiterates portions of the brief, stating that "the retail merchants in the District of Columbia have storage and han-

dling facilities more than adequate to supply coal to the government departments at all times, as well as to serve the local trade.

"The operating costs of the Government Fuel Yard have conformed to the 'government system of accounts,' but they have not included all direct or indirect costs of doing business," says Mr. Stephens. "Although the published cost for the period July 1, 1916, to June 30, 1921, was slightly less than \$1 per ton, the real cost per ton to the government of unloading cars, storage and delivery, including indirect overhead expense, arrived at after complete agreement between officials of the Bureau of the Budget, Government Fuel Yard and National Retail Coal Merchants' Association, for the same period was found to be \$1.78 per gross ton. Therefore by turning this business over to the retail dealers, at their agreed figure of 92c. per gross ton, the government will effect saving of 86c. per ton, or upward of \$1,000,000 in the period covered by the attached bids."

Pittsburgh-Great Lakes Co. Merger in Ohio

Merger of the Ohio properties of the Pittsburgh Coal Co. and the properties of the Great Lakes Coal Co., which had been operated by the Columbus (Ohio) office of the Pittsburgh Coal Co., has been completed under the name of the New Pittsburgh Coal Co. Papers of incorporation have been taken out at Columbus and the new company, with an authorized capital of \$2,100,000, will have charge of the operation of all properties and the sale of the product. The general offices will be in the Rowlands Building, Columbus, with C. G. Weitzell as president and J. A. Rundio sales manager.

The property consists of large mines in the Hocking Valley, eastern Ohio field, Pomeroy Bend field and in Kentucky. The Kentucky property has one operating mine with a capacity of 2,000 tons daily at Betsy Layne, on the Big Sandy division of the Chesapeake & Ohio R.R. This property will be further developed to a point where the output will be 5,000 tons daily. The eastern Ohio mines are on the Wheeling & Lake Erie and are located in Harrison, Jefferson and Belmont counties. The Hocking Valley mines are on the Hocking Valley R.R. and the Pomeroy Bend mines also are important operations. The Great Lakes Coal Co. formerly was a P. Reiss interest. The merger became effective Jan. 1.

COMPARISON OF PRESENT FUEL YARD COSTS WITH THOSE NECESSARY UNDER TERMS OF DEALERS' PROPOSAL

Proposed Plan		Present Plan	
Dealers' average bid for unloading, trucking and delivery.....	\$0.920	Fuel Yard legal cost fiscal year 1923.....	\$0.850
Cost to government of coal purchase, auditing, bookkeeping, etc. (At new compensation schedule rates for force employed).....	0.120	Degradation cost on anthracite.....	0.006
Cost to government of weighing and inspecting coal as required by Act March 15, 1898.....	0.080	Indirect cost to taxpayer.....	0.372
Cost to government of inspecting deliveries and storage.....	0.024	Interest on liquid capital \$200,000 at 5½%.....	0.056
Cost to government for demurrage and guarantee of railway weights.....	0.100	Total cost per ton to taxpayer.....	\$1.284
Investment less if yard be abolished, prorated on coal deliveries of five years.....	0.479		
Interest at 5½ per cent on liquid capital of \$200,000.....	0.056		
Total cost per ton to taxpayer.....	\$1.779	Net loss per ton to taxpayer.....	0.495
Total cost per ton to taxpayer if yard be kept in standby condition and deliveries resumed at end of period.....	1.660	Net loss per ton to taxpayer.....	0.376

Supreme Court Sustains Recapture Clauses

The right of Congress to divert the earnings of the stronger railroads to the relief of the weaker, as provided for in Section 15A of the Transportation Act—known as the "recapture clauses"—was declared constitutional in an opinion handed down by the U. S. Supreme Court Jan. 7. Chief Justice Taft wrote and read the opinion. The Dayton-Goose Creek Ry., a small line in Texas, was the complainant, but nineteen of the largest railroads in the country joined in the contention that the recapture clauses were invalid. Chief Justice Taft, in his opinion, upheld the Federal Court for the Eastern District of Texas, which dismissed the original complaint by the Dayton-Goose Creek company.

Southern Gem Corporation In Hands of Receivers

The Southern Gem Coal Corporation, of Chicago, is in the hands of receivers. On Jan. 2 Federal Judge English, in East St. Louis, granted the petition of W. S. Wilson, of Pinckneyville, Ill., and seven other creditors and appointed Mr. Wilson, a veteran Illinois coal man, and Judge C. B. Thomas, a federal referee in bankruptcy, as receivers. Officials of the Southern Gem Corporation said they had had no notice of the petition and that since the major creditors and stockholders of the concern were not in favor of the receivership, they probably would ask the court to lift it. The corporation has been operating mines in several Illinois counties.

Simon Levy, of the Boylston Coal Co. of Chicago, a direct-to-consumer dealer, who signed a five-year contract for the entire output of the two Franklin County mines of the corporation, thereby putting about 1,500,000 tons of Franklin County coal into snowbird trade, said he thought his contract was bullet-proof and that the receivership would not interfere with the delivery of the coal to him. He said on Jan. 5 that deliveries had already started. Others interested said the receivership doubtless would upset the snowbird contract, which has caused such consternation among Illinois coal men.

In the receivership petition, signed by Mr. Wilson, the Wilson-Richey Stores Co., Sherman S. Richey, W. T. Richey, William Crawford, George F. Meade, Ephraim Cliburn and Alex Wilson, it is set up that the Southern Gem Coal Corporation is bankrupt through mismanagement and the payment of exorbitant salaries to officials and that bond issues have been floated on the Perry County mines and on the two Franklin County mines in order to prevent payment of creditors' claims. The receivers took over control of the mines as well as the Wabash, Chester & Western R.R., a short line in southwestern Illinois, a large lumber company, an insurance company, an automobile sales agency and a sales agency for handling the coal.

Slidin' on the Levee

River coal operators on the levee at Louisville, Ky., had their troubles on Jan. 2, when the levee was covered with glaze, from a freezing rain. Trucks could not negotiate the hill from the water level, and about a dozen trucks and cars were pulled out of the river during the morning, after making long slides on the ice. One sliding pleasure car is reported to have kicked three trucks into the river.

Says Union Favors Ohio to Detriment of Kanawha

Kanawha operators, speaking through D. C. Kennedy, secretary of the Kanawha Coal Operators' Association, assert that conditions have been imposed on them by the union which make it much more costly to produce coal than in Ohio mines. As an instance, it is pointed out that in Ohio 70 per cent of the men employed are tonnage workers. In the Kanawha field the percentage is but 54.

More helpers have to be employed in the West Virginia mines, Mr. Kennedy contends, than in the Ohio mines, it being pointed out that in the mines of the latter state car tracks are laid to the opening of rooms, the miners being required to lay the tracks back to the face of the coal, whereas in West Virginia all tracks are laid to the face of the coal for the miners. This necessitates the employment of additional labor. Helpers or assistants are required to be furnished in West Virginia, it is claimed, but not in Ohio. Because of the necessity of employing more labor, Kanawha operators assert that the cost of production is greatly increased and that such an increase in

Germans Get North Dakota Lignite Fields?

It is reported that August Thysen, of the Mannheim (Germany) firm of Thyssen & Co., has taken options on lignite fields in North Dakota and will engage in the production of briquetted lignite under a new German process. Dr. Hans Holzwarth, chief engineer for the firm, has been in Minneapolis, Minn., after a trip of inspection of the lignite fields, and is said to have taken options on some promising lignite fields. A rotary distillation process, which recovers numerous byproducts and produces a "hema-coke" is to be used. This coke is ground and briquetted with pitch recovered from the raw material. It is asserted that this product can be produced and sold in the Twin Cities at \$8 a ton. It is also possible that machines for the process will be manufactured in this country, possibly in the Twin Cities.

the cost of production constitutes another handicap to reasonable competition with coal mined in Ohio.

A conference has been called for early in January between a committee from the International office of the United Mine Workers and D. C. Kennedy, secretary of the Kanawha Coal Operators Association, with a view to ironing out the existing inequalities.

Bay State Coal Committee Presents Findings

The Joint Special Coal Investigating Committee, appointed by the Massachusetts Legislature to probe the coal business, in a report just released, finds among other things the following:

(1) The Legislature cannot assure a continuous and adequate supply of anthracite.

(2) Adoption of lower-cost fuels, especially bituminous coal, by the public is the way to meet the problems of fuel supply.

(3) There is no justification for the \$16 retail price asked for domestic coal by Boston retailers, as the maximum should be not more than \$15.50.

(4) There should be federal legislation providing for complete publicity with respect to the anthracite industry, this including operators, sales organizations, transportation companies and the miners' union.

(5) The President should be authorized, in case of actual or threatened suspension, to name a special commission of inquiry and conciliation.

(6) The contract between operators and the union should be amended to provide penalties in case of a breach by either party.

(7) Congress should authorize some federal agency to standardize anthracite sizes and quality.

(8) In case of a fuel emergency the Interstate Commerce Commission or some other federal agency should receive power to prevent speculation in coal by jobbers and wholesalers.

(9) The State of Pennsylvania should repeal "the now notorious anthracite tonnage tax."

Rail Coal Consumption Heavy During October

Class 1 railroads of the United States consumed 9,411,000 net tons of coal during October, 1923, as charged to account 394, compared with 8,521,000 tons in the preceding month and 9,281,000 tons in October, 1922, according to a report by the Bureau of Statistics of the Interstate Commerce Commission covering 176 steam roads. During the first ten months of 1923 these roads consumed 91,715,000 tons as compared with 76,159,000 tons in the corresponding period of 1922. The delivered cost per ton in October last was \$3.30 as against \$4.26 in October a year ago.

Consumption of fuel oil during October was 198,760,000 gallons, compared with 175,943,000 in the preceding month, and 154,749,000 gallons in October, 1922.

Oddie Legislation to Provide Minimum Federal Role in Coal Industry

Nevada Senator Discounts Proposals to Fix Prices and Limit Margins — Sees Need of Assistance—Constructive Report of Massachusetts Commission Occasions Surprise

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

In introducing legislation suggested by the report of the Harding Coal Commission, Senator Oddie will not follow exactly the recommendations which the commission put forward. The Nevada Senator, who is chairman of the Committee on Mines and Mining, to which the Coal Commission's report was referred, has not determined finally the exact provisions he will put forward in the legislation that he will introduce. He is much impressed with the intricacy of the problems presented, but he views with particular approval those features of the commission's recommendations which emphasize the need for fostering and developing the coal industry in putting it on a stable basis.

As a man familiar with the problems of actual mining, he is inclined to discount the proposals for regulation, which include price fixing, limitation of margins and the like. He has not committed himself as yet as to just how far he is willing to suggest any extreme measure until other means have had a fair trial. He recognizes that the important thing to be accomplished is to insure the public of a constant and adequate supply of bituminous coal. If that can be accomplished, he believes prices and profits will take care of themselves.

Senator Oddie is thoroughly convinced that the coal industry needs the same sort of careful assistance which he is proposing for the mining industry in general in his bill providing for the establishment of a Department of Mines.

It is evident that the views of Senator Oddie are at variance with those of Representatives Treadway, Luce and Rodgers, and with those of Governor Pinchot.

In connection with the legislation suggested by the New England members of the House of Representatives mentioned, it is pointed out that the report of the Massachusetts commission appointed by the Legislature of that state takes a more constructive position. It does not advocate limitation of margins, fixing of prices, nor other extremes of legislation, although it does advocate publication of essential facts through a central agency with powers to prescribe forms of accounts.

The restraint and good sense which is shown in that report came as something of a surprise to Washington, which has been accustomed to expect rather radical suggestions from New England. The outbursts of certain members of Congress from that section are regarded with much tolerance because it is realized generally that their section

of the country has gone through some very disagreeable experiences.

If the report of the Massachusetts committee correctly interprets the feeling of the people of New England, it would indicate that they believe some federal action is necessary, but that they are not ready to go to the length of putting coal on a public-utility basis.

While the legislation Senator Oddie is drafting is certain to reflect his interest in a Department of Mines, it is known definitely that it will provide for a minimum amount of federal intervention in the conduct of the coal business.

As a step toward obtaining a Department of Mines, a compromise proposal is being considered. It is quite evident that the addition of a Secretary of Mines to the Cabinet can be effected only after a hard fight, which, necessarily, must extend over a considerable period. An important step in that direction, however, would be marked by the simple addition of the two words "and Mines" to the "Department of Commerce," making the official designation of that branch of the executive machine read "Department of Commerce and Mines."

The early transfer of the Bureau of Mines to the Department of Commerce seems probable. The President is committed to a policy of strengthening the Bureau of Mines. Arrangements already are being made for increased activities on the part of that bureau. If while these changes are being made, the designation of the department can be changed as mentioned it will give increased recognition to the mining industry by the federal government and will mark great progress toward a separate department that will deal with mining matters only.

Governor Smith Says New York Can't Handle Coal Situation

In his address to the Legislature on Jan. 2, Governor Smith referred to coal in the following words:

"This time a year ago the state was suffering from a shortage of coal due to a prolonged strike at the mines and we were obliged to invoke the extraordinary police powers of the state for the protection of our people. While there is no shortage apparent at this time the price of coal has been increased to meet settlements made because of another strike threatened during the month of September.

"In my opinion the coal problem is one we cannot handle in this state ef-

fectively. No coal is mined in the State of New York and costs of production, taxation by the state where it is mined, and the rates fixed by the Interstate Commerce Commission are all entirely outside of our control. We can only turn the searchlight of public opinion on those who would take advantage of the situation to profiteer. We have done this by creating the fair-price coal commissions in the various cities where it has been certified to me by the chief executive of the municipality that conditions warrant it.

"I call this to your attention at this time in order that appropriate committees of your honorable bodies may have the matter under consideration so that if an emergency should arise through shortage or failure of adequate transportation, the state may be ready at a moment's notice to take such action under our police power as might be required for the preservation of the public health."

Says Searles Is Preparing "Usual Alibi"

Walter H. Cunningham, secretary of the West Virginia Coal Association, commenting on the statement attributed to Ellis Searles, editor of the *United Mine Workers Journal*, that the non-union operators are trying to bring about a strike in union fields in order to make unholy profits, said: "Searles has adopted the same publicity tactics that marked the preliminary phases of the union miners' walkout in 1922. It would appear it has become the fixed policy of union officers to provide in advance an alibi and thus maneuver into a position where they can take advantage of their own misdeeds.

"The charge that non-union operators of southern West Virginia are attempting to force a suspension of work in the union fields is as ridiculous as his charge that operators 'made millions of dollars in unholy profits in the strike of 1922.' Operators in the non-union districts have no more control over events in the union coal fields than they have over the actions of the officers of the United Mine Workers of America."

CHARLES H. DORRANCE HAS RESIGNED his position as vice president in charge of operations of the Hudson Coal Co., with offices at Scranton, Pa., because of ill health and need of rest. Mr. Dorrance's duties will be taken over by A. M. Fine, who will also continue as vice president in charge of the auditing department.

BIDS FOR FURNISHING and delivering 10,000 gross tons of bituminous coal for navy vessels will be received by the U. S. Navy Department at Washington on Jan. 16. The coal is to be delivered as needed alongside ships New York harbor or at the Brooklyn Navy Yard and must conform to the following analysis: Volatile, 23 per cent maximum; ash, 7 per cent maximum; sulphur, 1.5 per cent maximum, and B.t.u., 14,700 minimum.

Davis Invited to Address Union Miners' Convention

James J. Davis, Secretary of Labor of the United States, has been invited to make an address the first day of the annual convention of the United Mine Workers in Indianapolis, Jan. 22. About 1,800 delegates are expected. Officials of the union say it is impossible to say at the present time just what the wage demands of the miners will be, that question being entirely in the hands of the wage-scale committee and the body as a whole, but they say that no cut in wages will be countenanced.

Last year more than 600 resolutions were submitted on wage and working conditions alone and officials expect as many this year. A change in the method of allotting delegates will reduce the number at the convention this year by about 400. More than 2,200 delegates were present at the last convention. The same number of votes will be in evidence, however, a delegate being empowered to declare all the votes he represents.

Buyers' Year Ahead Is Opinion Of Statisticians

The real purpose of the American Statistical Association meeting in Washington recently was to discuss forecasting in business and the prospects of 1924. This gathering, which included many of the brightest minds engaged in statistical work, reached the conclusion that 1924 promises to be very much like 1911. An analysis of the situation at the close of 1910 shows that much the same influences were at work at the close of 1923.

On that and other assumptions, it seems to have been the consensus of opinion that 1924 will follow a course midway between prosperity and depression. There will be little unemployment. Wage schedules will undergo little change. Price fluctuations will be small. Business will be cautious but not dull. Competition will be keen. The volume of business will be less than in 1923 but will be greater than that of 1922. It will be a buyers' year, rather than a sellers' year.

The thought of the meeting with regard to coal seems to have been that it will be a year of serious competition, one in which the public may expect an ample supply of coal at reasonable prices provided it does its part in spreading purchases evenly enough throughout the twelve months to prevent a peak in the fall, which the railroads would not be able to handle.

R. M. RANDALL, of Saginaw, Mich., general manager of mines for the Consolidated Coal Co. of Michigan, died Jan. 1. For years he had been the operating head of the company's four Michigan mines, producing nearly half a million tons of coal annually. He represented the company, and usually the State of Michigan, in all labor negotiations and was a vice-president of the National Coal Association.

International Mine-Rescue Meet at Huntington

Huntington, W. Va., has been selected by the U. S. Bureau of Mines as the place for holding this year's International First-Aid and Mine-Rescue Meet. The meet probably will be held in September.

Winslow to Draft Coolidge's Coal Plan for House

Legislation representing President Coolidge's views on coal and transportation problems are to be placed before the House soon by Representative Winslow, of Massachusetts, chairman of the House Committee on Interstate Commerce, before which such matters come. At a conference Jan. 3 the President clarified the administration policies as set forth in his message to Congress. As a result of the conference Representative Winslow intimated that he would draft bills embodying the President's ideas for presentation to his committee this week.

Mr. Winslow said that the President advocated the establishment of a commission empowered to deal with future emergencies in the coal industry, the bringing about of greater unity in the ownership of coal mines and the formation of common coal-selling agencies for limited districts.

The administration legislation also will cover consolidation of the railroads, both regional and route, providing federal machinery for the stimulation of such consolidation and will propose a reorganization of freight rates.

Bituminous-Wage Parley Feb. 11 in Florida

Union representatives and operators of Ohio, Indiana, Illinois and probably western Pennsylvania will meet at Jacksonville, Fla., Feb. 11 to negotiate a new wage agreement for bituminous-coal miners, to become effective April 1. This was agreed upon at a meeting of representatives of the miners and operators of Ohio, Indiana and Illinois held in Cleveland, Ohio, Jan. 4.

Western Pennsylvania was not represented at the Cleveland meeting but in the call to be issued for the Jacksonville conference the miners and operators of that state will be included. It was specified at a joint conference in New York last January that in case a wage scale meeting is called this year all four states be included, despite the fact that the western Pennsylvania men are not signatories to the present wage agreement, which expires March 31. If western Pennsylvania declines the invitation, a three-state conference will be held.

Treadway Presents Coal Bill In Trust-Busting Speech

Something of the temper of the House of Representatives may be judged from the fact that it burst into applause when Representative Treadway, of Massachusetts, in the course of an old-fashioned trust-busting speech, declared that he agrees heartily with Governor Pinchot in his expression that the company operations in Pennsylvania constitute a "hard-boiled monopoly, whose prime interest in the public is that it shall consume their coal at their price." There also was vigorous applause for his demand that the anthracite companies be required to give publicity to their accounts. He did not spare the mine workers in his excoriation of the anthracite industry. He condemned the state license system and the limitation placed upon output.

Representative Treadway reviewed such portions of the Coal Commission's report as supported the bill which he has introduced. He was not particularly complimentary to the Coal Commission, but declined to concur in an expression by Representative Blanton, of Texas, that \$600,000 had been spent on a useless commission. He contended that the federal government is the only agency which can grapple with the situation with any hope of success. He expressed himself as being against government ownership, but feared the public demand eventually will be such as to force it. Mr. Blanton again interrupted to say that government ownership would mean a cost at the mine of \$25 a ton.

Corona Co. Files Two Appeal Writs; One Dismissed

The writ filed by the Corona Coal Co. of Alabama, to appeal from a decision of the Court of Claims in a suit against the U. S. Railroad Administration was dismissed Jan. 7 by the U. S. Supreme Court on the ground that the company had also filed suit in a federal district court and that it could not proceed by both methods. The company had a contract to supply coal to several railroads. When the Railroad Administration took over the carriers it attempted to enforce the contracts, but this was denied. The Fuel Administration then requisitioned the coal. The Railroad Administration paid the contract price for the coal it used. As this price was lower than the price declared fair by the Fuel Administration, the Corona company sought to collect the difference.

THE INTERSTATE COMMERCE COMMISSION has called a hearing in Minneapolis for Jan. 17 in connection with the protest against withdrawing the joint-all-rail rate on anthracite. If the joint rate is withdrawn and the sum of the locals applied, it will cause an increase in freight of \$1.66.

Practical Pointers For Electrical And Mechanical Men

Explanation of Fan in Electrical Terms; Increasing Efficiency with New Drive

A shunt-wound generator driven at a certain speed produces a certain pressure or voltage, which as long as the speed remains constant will be reduced only by the resistance to the current flowing through the generator winding itself. The amount of this current will depend on the resistance of the external circuit or path connected to the generator, the resistance of this path being proportional to its length and inversely proportional to its cross-section. Similarly, the mine ventilating fan driven at a certain speed produces a certain pressure or water gage which as long as the speed remains constant will be reduced only by the friction of the air flowing through the fan itself, and the amount or volume of this current of air will depend on the resistance of the external path connected to the fan, the resistance of this path being proportional to its length and inversely proportional to its cross-section.

The water gage as generally read, as being the friction drop in the mine, corresponds to the drop in voltage in the electrical circuit. The greater distance the current of electricity or air is to be carried, the greater the pressure that is necessary to force it through the circuit whether it be an electrical conductor or a mine gangway. To produce greater pressure either the armature or fan must be run at a higher velocity or the diameter must be greater to produce a higher peripheral speed. If the electric current or current of air is to be greater than a greater path area is necessary both internally and externally if the flow is to be produced efficiently—that is, the generator must have a larger area of conductor, whether it be obtained by one large conductor or several smaller

ones in parallel, and the fan must have a larger area whether it be widened out or have multiple inlets, to give a larger air passageway. The method of obtaining greater area of section to permit the flow is similar in the external path—that is, one large path or several smaller ones in parallel.

If a generator were purchased to produce 250 volts and 1,000 amperes, it would not be expected to produce either 500 volts or 2,000 amperes, even disregarding the efficiency; in fact, the generator, if not protected by fuse or circuit-breaker, probably would burn up, while the fan, if driven by a motor or engine of sufficient power, would continue to operate, but inefficiently.

If the generator is operating with a heavy load and the pressure is low at the end of the line, tests are made for

short-circuits, the area of conductors is checked and if small is increased, and if conditions are such that the generator is still overloaded, additional capacity is installed; but in the case of the fan, in many cases it is speeded up and made to run inefficiently and given no further consideration.

In the case of the generator, the current forced out by the pressure must return to the generator, and as no efficient path has been provided by nature we are forced to provide a path of sufficient area. By sinking a shaft at the far end of the mine we are enabled to use a path of infinite area for the fan return.

Because in many cases the power cost of pumping and ventilation is 60 per cent of the total power cost, it appears that greater care should be taken to make the fan deliver its air efficiently. Short-circuits in the air course and restricted air courses will show only in the power bill, unless accurate instruments are installed and readings carefully noted.

The following are tests made on a number of fans scattered throughout the coal region: Fan 6 ft. x 3 ft. 6 in. installed on shaft, delivering 105,000 cu.ft. of air per minute; water gage, 2.9 in.; input to motor, 180 hp.; in the air, 48 hp.; efficiency of installation, 26½ per cent. Fan 6 ft. x 3 ft. 6 in. installed on shaft, delivering 66,300 cu.ft. of air per minute; water gage, 3.6 in. input to motor, 142 hp.; in the air, 37.6 hp.; efficiency of installation, 26.4 per cent. Fan 6 ft. x 3 ft. installed on drift, delivering 60,000 cu.ft. of air per minute; water gage, 0.5 in.; input to motor, 9 hp.; in the air, 4.7 hp.; efficiency of installation, 52.2 per cent. Fan 4 ft. x 2 ft. 6 in. installed on shaft improperly located, delivering 45,000 cu.ft. of air; water gage, 2.5 in.; input to motor, 42.9 hp.; in the air, 17.7 hp.; efficiency over all, 41.3 per cent.

For one of our new fans 90,000 cu.ft. of air per minute was necessary, so a new shaft was sunk at the proper location and a 6 ft. x 3 ft. Jeffrey fan installed. As the fan could be run at reduced speed at night and on idle days, a General Electric variable speed brush-shifting motor was connected to the fan. This motor was arranged to run from 100 to 243 r.p.m. with windings in star and from 243 to 450 r.p.m. with windings in delta, the motor being direct-connected to the fan. The curves show that the 90,000 cu.ft. was obtained with an input to the motor of 60 hp., and if this had to be obtained with the old

Much of the mine power bill is due to the fan; therefore any saving in efficiency in the fan and motor drive is highly desirable and soon pays for itself. These curves cover a modern fan and a brush-shifting motor.

installation it would have required 350 hp. input. This fan was installed in a position where at some future date it will be used to ventilate an adjoining mine.

It would seem that the ventilating system of the mine should receive the same careful study as the electrical system; otherwise it will be found that in many cases the flow will be sufficient but the efficiency very poor.

J. F. MACWILLIAMS,
Electrical Engineer.

Pennsylvania Coal & Coke Corp.,
Cresson, Pa.

Almost a Serious Accident on Ungrounded Machine

Several days ago I was sent to a coal mine in one of the Southern states to locate and repair some trouble on a motor-generator set. The generator was a 275-volt machine and the motor operated at 2,200 volts. The details of the trouble were not given me, so I had no idea what the trouble was. After reaching the substation, which was about 2,000 feet underground and in an extraordinarily dry place for a coal mine, I began my investigation.

The substation equipment was enclosed with a wire fence and the superintendent reached over and touched the machine which was still running, explaining to me at the same time that it shocked anyone who touched it. Several of the other men who were to help repair the machine touched it also. Seeing that they were not seriously shocked I touched it with the back of my left hand.

My conclusion was that the d.-c., or low-voltage, side of the machine was grounded slightly. But when the machine was shut down there was no ground found on the d.-c. end. Accordingly the motor winding was tested and showed a dead ground. We had all been flirting with death, handling 2,200 volts while standing on the ground. I looked around the machine for a ground wire but it had not been installed, nor was there a ground to the switch framework. I cleared the ground on the motor by cutting out a defective coil. Then I reported the lack of a ground wire and its function to the superintendent. He promised to see that the machine was properly grounded the next day.

If any of the attendants of that substation had been killed or injured I have no doubt that if the case were taken to court it would return a verdict of "criminal negligence" on the part of the company operating the station ungrounded.

The importance of grounding apparatus which is classed as high-potential electrical machinery cannot be overestimated, especially around a mine, where the earth generally is damp. To leave machinery of this class ungrounded is to break both the mining laws and the laws of the Underwriters. Following is a list of the sizes of wire

to use for grounding purposes as specified by the Board of Fire Underwriters:

SIZES OF WIRE REQUIRED FOR GROUNDING

(As listed by National Board of Fire Underwriters Under Rule 15A Section m)

Capacity of Nearest Cutout Protecting the Equipment	Size of Ground Conductor
0 to 100 amp.	No. 10 B & S gage
101 to 200 amp.	No. 6 B & S gage
201 to 500 amp.	No. 4 B & S gage
500 and above	No. 2 B & S gage

The above is for copper wire only. The place of connection should be in plain sight. A piece of trolley wire is all right for a ground wire.

GRADY H. EMERSON,
Birmingham, Ala. Electrician.

Charges to Capital and Maintenance Accounts

One thing that the Coal Commission noticed in its survey of the coal industry was the lack of definite information of the capital invested at the coal mines. Only the larger companies have any system whatever of knowing just how much capital investment they have in their property and what the maintenance costs on the plant are.

It certainly is not proper to charge all the expenditures for equipment and changes to the mine plant to the capital account. Most mining expenditures may be charged either to capital or to maintenance, but some charges require considerable thought before the proper amount can be charged to either of these accounts.

Another important consideration is the charging off of the value of portions of the property which have been abandoned or which have become obsolete. Unless this is done the capital charge will reflect a much higher investment than could actually be considered the capitalization of the property.

Charges for work done on contract usually are very easily placed against capital account. Maintenance charges, such as are ordinarily necessary for the upkeep of the equipment, easily fall into their proper class. Some large companies have authorization forms for all new work. Before any material or labor is done on the job, instructions are given as to what class the work falls under. However, the charges cannot be made until the work is done, since, depending upon the charges and the extent of the work, certain amounts must be charged to either the capital or maintenance accounts.

To decapitalize a part of the investment, a report is made and forwarded to the controller's department. Here a trace is made to ascertain positively the amount of the decapitalization and its value. Due to the ever changing costs of materials it is often a question as to the value of the decapitalized property or material. Nevertheless, an accounting department following up this work usually would have little difficulty in writing off the proper value.

Sealing a Centrifugal Pump Against Air Leaks

Everyone knows the importance of preventing air entering a centrifugal pump. Once air enters the pump it causes several difficulties; most important, however, is the fact that it cuts down the capacity and makes the pump rattle. Depending upon the design of a pump, air leaks happen at joints and pump connections and through the stuffing boxes. Air leaks in pipe connections are not always obvious, while leaks at the stuffing boxes are more easily traced.

In horizontally split pumps the connection between the upper and lower parts of the casing often are neglected and cause air leaks which usually are not easy to find. In taking the pump apart the gasket between the two parts frequently is broken, thus causing ridges and leaks.

To avoid the breaking of this gasket and thus to keep the joints free from leaks, our company has made a practice of using a heavy paper gasket and thoroughly shellacking it to the lower half of the casing. When this shellac has dried the upper surface of the gasket is thoroughly soaked with a lubricating oil. The upper half of the casing is then placed on top of the oiled surface and the two parts are tightly bolted together. The oil tends to some extent to soften the paper and at the same time fills in the pores or slight imperfections in the castings. In this way a very tight joint is made and when the upper half of the casting is removed from the pump, the separation is made without damaging the gasket. By proper care the same gasket can be used several times and yet never be broken.

MINE MECHANIC.

One kilowatt equals:

1,000	watts.
1.3410	horsepower.
2,655,180	ft.-lb. per hour.
44,253	ft.-lb. per minute.
737.56	ft.-lb. per second.
3,415	heat units per hour.
56.92	heat units per min.
0.9846	heat units per second.

22.77	lb. of water raised from 62 deg. to 212 deg. F.

Problems In Underground Management

Would Ventilate Mine Fire Area With Inert Gas

Why Stopping Intake Is Inadvisable—Small Fire Area If Shut In May Explode—Can Extinguish Crop Fires Only If Dead Air Is Driven in Fast Enough to Keep Surface Air Out

BY JOSEPH J. WALSH

Secretary of Mines, State of Pennsylvania, Harrisburg, Pa.

When sealing a mine fire in a gaseous mine, the question whether the return or the intake seal should be erected first frequently arises. Various answers are given to this question, depending upon conditions in the mine.

Under any condition it is an extremely dangerous practice in a gaseous mine to erect the intake seal first. This is particularly true if an exhaust fan is used, for the reason that when the intake seal is erected first, the gases generated by the fire are free to move to the fan, and any firedamp that may accumulate in the air course leading to the fire will move, of course, in that direction and become ignited.

On the other hand, if the return stopping is erected first, the gases generated by the fire will spread in all directions, forming a zone of inert gases around the fire, thus creating a condition that will not support the combustion of methane or firedamp.

It is a hazardous undertaking to seal a small fire in a gaseous mine, because it cannot generate sufficient inert gases to create a zone sufficiently reduced in oxygen to prevent the explosion of firedamp. If a fire is known to be small and must be extinguished by the sealing method, fresh air should be applied, if necessary, until the fire extends across the face of one chamber, at least. The size of a mine fire can be determined readily even though it is inaccessible and cannot be seen.

The conditions, however, surrounding the crop fires render their sealing of little value. It is practically impossible to exclude fresh air from these fires because of the broken strata and the closeness of the fire to the surface.

For extinguishing fires of this nature I propose the inert-gas method, that is ventilating (if we may use the term)

the affected area with a gas consisting chiefly of nitrogen and carbon dioxide, together with small percentages of carbon monoxide and oxygen, the latter being in such small proportion that they will not support combustion.

In order that this system may be used successfully it is necessary that the gas be forced into the mine with a force sufficient to create a pressure within the fire area greater than the pressure of the atmosphere surrounding this area. When this is done, every opening or crevice leading from the surface into the fire section will be converted into an outlet for the inert gas, thus assuring the exclusion of fresh air. In other words, all the openings through which fresh air might enter the mine will be sealed by the inert gas.

This gas would be generated simply by burning the oxygen out of the air. The products of combustion then would be passed through a cooling system, thence to a fan, by means of which they would be forced into the mine.

ESTIMATION OF PLANT NEEDED

The size of the plant, of course, would depend on the volume of gas required each minute. For example, assuming that a plant capable of producing 10,000 cu.ft. of gas per minute is required, four furnaces with grates 7 ft. wide and 6 ft. deep would be necessary, these being arranged in batteries of two furnaces to the battery.

The grates should be of the dumping type, as the low carbon dioxide and high oxygen prevailing during fire cleaning make it essential that these periods be curtailed as much as possible, and this can best be attained by the use of dumping grates. The furnaces should be provided with a blast equipment capable of supplying 10,000 cu.ft. of air at a suitable water gage, and with appropriate dampers, so that the furnace may be isolated at will.

The hot gases from each furnace will enter a firebrick-lined header, from which it will be distributed to six cooling flues about 35 ft. long and 18 in.

in diameter. These cooling flues will be immersed for 30 ft. of their length in a tank of cooling water. The partly cooled gases will be gathered at the far end of these cooling flues and conducted through an airway to the cooling tower.

The purpose of these flues is to give the gases a preliminary cooling so that the latter may be handled without difficulty. The inert gas leaving the furnaces will be at a temperature of about 2,200 deg. F. and these flues are designed to drop this temperature to about 600 to 700 deg. F. This partly cooled inert gas will enter the base of a cooling tower 30 ft. in height and 16 ft. in diameter, constructed of hollow tile. In this cooling tower its velocity would be reduced to about 50 ft. a minute.

GAS COOLED TO 80 DEG.

Five feet from the top of this tower sprays would be provided that would discharge 400 gallons of water per minute at a pressure of $7\frac{1}{2}$ lb. to the square inch into the ascending hot gas, dropping its temperature to about 80 deg. F. The cooled gas would leave the tower at its top and be carried by a downcast to its base, where a fan capable of producing 10,000 cu.ft. of air per minute at a 3-in. water gage would deliver it for distribution to the mine workings. The hot water leaving this cooling tower might be used to supply the preliminary cooling tank, and it might be advantageous to locate the tower at such a height that this water would flow by gravity to the cooling tank.

If we assume that 1 sq.ft. of fire grate will consume 20 lb. of coal each hour, the area of a fire grate that will consume sufficient coal to produce 10,000 cu.ft. of an inert gas per minute may be found as follows:

Admitting a 30-per cent excess air supply to the furnace 1 sq.ft. of fire grate consuming 20 lb. of coal each hour would produce each minute:

$$\frac{16.6 \times 20}{60} = 5.5 \text{ lb.}$$

or 72 cu.ft. of gas. To produce 10,000 cu. ft. of gas each minute a grate area will be required of

$$\frac{10,000}{72} \text{ or about } 140 \text{ sq.ft.}$$

The coal used in a plant of this size, after making an allowance of 30 per cent for the coal wasted, would be about 4,000 lb. per hour.

Article entitled "Mine Fires and Some Methods for Extinguishing Them," delivered before the Coal Mining Institute of America, Dec. 20, 1923, at its Pittsburgh meeting. A description of this method, without many details which Mr. Walsh has since added, was contained in an article which appeared in *Coal Age*, Feb. 23, 1922, pp. 328 and 329.

Discussion

Operators Should Formulate Better Laws That Coal Mining May Be Made Safe

A member of the American Association of Labor Legislation in giving his views has found some who do not agree with him on additional legislation as a means of enforcing safety in mines, especially where he favors abolishing the use of black powder from mines, and again where he advocates placing police power in the U. S. Bureau of Mines. One writer in answer says that there are now few mines where permissibles should be used that are not using them and says further that resistance doesn't come from the operator so much as from the miner and that safety is to be obtained through education rather than legislation.

One can readily agree that education is the foundation of safety, for, broadly speaking, education is the foundation of all things, but I believe we will all agree that the education of the individual is a slow process, so slow in fact that little can be accomplished. For this reason it would be well to consider educating legislators rather than individuals and through wise legislation enforcing safety on those who oppose it. This would be preferable to placing police power in the Bureau of Mines. The operators in mining states should meet the legislators at every session and discuss what legislation should be passed to lessen the dangers of mining.

No doubt there are legislators in some mining states who are familiar with mining needs, but the number in most of these probably is small. When the draft of a mining law is presented it usually is held over for further discussion, which means that the legislators do not know how to act on it, and in consequence the draft is never enacted into law. Going back over my own experience, I can recall few instances where anybody took the initiative in revolutionizing any phase of mining so as to enhance its safety. I can recall, on the other hand, that almost every important step in safety has been enforced through legislation.

The attitude that the average individual takes is, Does the law say I must do this? or Can the law compel me to install this or that safety equipment or practice? The truth is, most of our accomplishments in safety have resulted from remedial legislation, even though some mining men have taken the initiative and gone far ahead of all requirements of the law to make their mines safe and satisfactory to work in.

Education must continue—it would be a sad world without it—but nevertheless we will always have many individuals who will not consent to be edu-

cated into safety and can be reached only through the strong arm of the law. Pineville, Ky. GEORGE EDWARDS.

Workman's Share in Britain Exceeds Even 85 per Cent

As Paul Wooton has correctly stated, the original arrangement in the National Wage Agreement of Great Britain was that the net proceeds obtained by the coal operators should be divided between the employees and employers on the basis of 83 per cent and 17 per cent, but it actually works out 85 per cent to 15 per cent, as a number of items of necessary expense should be included, for in drawing up the agreement no allowance was made to the operator for such expenses as rent allowances and free or cheap coal to the workmen.

I have taken as my authority the annual report of the Secretary for Mines for 1922, and as a matter of fact practically all the data given in my paper were taken from pages 6-8 of that report, as I have stated in my article. The Secretary says in effect:

The gross proceeds left after all charges are paid other than wages and wages costs are commonly known as the net proceeds, and these are available for wages and profits, "and shall be shared in an agreed proportion which works out at about 85 to 15 per cent."

As a matter of fact, in 1922, on account of some of the districts being on the "minimum" for most of the year, the average for all the districts when worked out proved to be on the basis of 92½ per cent to 7½ per cent.

Pittsburgh, Pa. JOHN T. RYAN.

Sprayed Concrete at Bruceton

In the test explosion at the Bruceton Mine the U. S. Bureau of Mines sprinkled 600 ft. of entry with one pound of coal dust from the West Kentucky No. 9 seam per lineal foot of entry and by a blown-out shot of 4 lb. of F. F. F. black powder produced an explosion the flame of which extended

300 ft. beyond the point where the coal dust was sprinkled. Gunite had been placed on the inner portion of this entry on the roof and ribs and within a few feet of the face. On examination the coating was found to be everywhere intact, despite the severe test thus incidentally made on it.

Large Automatic Drop-Bottom Cars in Effective Service

In your Oct. 18 issue, p. 594, was an article in which reference was made to a statement of Frank Haas as follows:

"As regards bottom-dump cars, he believed that they could hardly be constructed safely in excess of 1½ or 2 tons capacity."

This is a rather serious criticism of the automatic drop-bottom car. I feel that it is my duty and yours to give publicity to the facts. Let me say, at least for the Sanford-Day Iron Works, that we have never had complaint in regard to the strength of this type of car except in regard to some bumper castings of defective steel. Furthermore, no weakness has since developed. One car was loaded with 11,200 lb. of pig iron with no noticeable deflection of the bottom doors.

Now, as to actual practice: After about seven years of continuous service the First Creek Coal Co., of Blue Diamond, Ky., which installed the first fifty cars of this type which we made, wrote us that their cars carried on an average 2½ tons of coal and that they sometimes have loaded 6 tons of slate upon them.

The 10-ton incline monitor of another coal company broke down and the management arranged to build up the sides of two automatic drop-bottom cars (with 2¼-in. round axles) until they held between 5 and 6 tons of coal each. These cars gave complete satisfaction until new monitors were built.

The accompanying table gives an incomplete list of corporations using automatic drop-bottom cars with the average loads carried by the cars.

This type of car can be built to carry satisfactorily 6 to 10 tons. As you will note, the average load of the U. S. Gypsum Co. is 6.75 tons. In fact cars recently have been designed with a capacity exceeding 200 cu.ft., level full.

Despite what Mr. Haas has said, no objection has been made to the strength of the car even when it is loaded in excess of 2 tons. The cars are used not only for coal but for limestone, iron pyrites and silver ore, and they are built to support a load that only a 3-in. axle will carry safely.

LOADS CARRIED BY DROP-BOTTOM CARS

Company	Post Office	Average Loads in Net Tons	Maximum Loads in Net Tons
Glogora Coal Co.	Stickney, W. Va.	3.00	4.00
Winona Coal Co.	Birmingham, Ala.	5.00	6.00
U. S. Gypsum Co.	Oakfield, N. Y.	6.75	7.42
Bear Canon Coal Co.	Trinidad, Colo.	3.00	3.80
Hardy Coal Co.	Panther, W. Va.	3.60	5.00
Helena-Straven Coal Co.	Straven, Ala.	2.60	3.00
Hanover-Bessemer Iron & Copper Co.	Fierro, N. M.	5.00	6.00
Silver Dyke Mining Co.	Niehart, Mont.	3.70	4.03

List as originally received contained 22 items.

Descent of Wintry Blast Stirs Coal Markets; Prices Are Not Affected to Marked Extent

A sudden drop in temperatures over the greater part of the country last week created a stir in the coal market, but failed to affect prices materially. Some industrial consumers who had delayed buying because of the inventory period were forced into the market, while demand for domestic coals took a sudden spurt.

Production of soft coal during 1923 was 545,300,000 net tons, according to the preliminary estimate of the Geological Survey. This was an increase of 123,032,000 tons over the previous year's output, and has been exceeded only by three years, 1920, 1918 and 1917. Output during the week ended Dec. 29 dropped to 6,684,000 net tons, the lowest figure for any week during the last year, and a decrease of 3,859,000 tons when compared with the previous week's production. The loss in output was due to the holiday as well as the stoppage of work the day before and the day after. Production, however, during the last three days of the week recovered to about the previous week's level.

Price Index Advances

Coal Age Index as of Jan. 7 registers 182, an increase of three points, when compared with the previous week, with an average price of \$2.20. There were increases in southern Illinois, Mount Olive, Springfield, Standard and Kanawha and slight decreases in eastern and western Kentucky and Pocahontas districts.

The Western markets felt the effects of the lower temperatures which spread over most of the country. There was a lively jump in demand, but prices showed comparatively little change. Retail dealers were soon cleaned out of supplies and shippers were called upon to ship anything they had. Mines operating on part time were soon operating to capacity. In Ohio there was an active demand for domestic coals and similar conditions were reported at Pittsburgh. There was no improvement noted in the steam-coal situation in New England.

and buyers continue to show the same lack of interest in the soft-coal situation as during the past several weeks. Trade along the Atlantic seaboard continues dull.

Hard-coal production took a heavy drop during the last week of the year, declining 754,000 net tons to 1,236,000 tons, while preliminary reports indicate an output of about 95,000,000 net tons for the year 1923, a decrease of about 3,000,000 tons when compared with 1918, but about 74 per cent more than 1922.

Quotations for independent domestic coals continue to go downward, accompanied by less demand. All sizes are easier and retail dealers in most parts of the country are in good shape to meet any immediate requirements. Pea coal continues easy and can frequently be gotten below company prices.

Soft coal dumped at the lower Lake Erie ports for Lake shipment during the 1923 season amounted to 31,446,823 net tons up to Dec. 30, an increase of 12,095,500 tons over 1922 and 8,275,374 tons over 1921.

The export market was quiet. Some inquiries are being received but comparatively little business was reported as closed. Dumpings at Baltimore during December amounted to 21,030 tons of cargo coal and 4,697 tons of coke, as compared with 59,349 tons of cargo coal and 4,050 tons of coke in the previous month. Dumpings for all accounts at Hampton Roads during the week ended Jan. 3 were 265,413 net tons, as compared with 357,110 tons the week previous.

Joy Reigns in Middle West

There is much happiness and activity in the Midwest coal trade at last. Winter came with a vengeance. At the end of the week the mercury had dropped repeatedly far below zero throughout the Chicago region and the Northwest trade territory. Retailers with small stocks on hand quickly emptied their yards and shippers shipped everything available. Mine tracks have been burdened with "no bills"

in all domestic sizes, so that producers were ready for the first burst of the demand. Not many changes of price were felt by the end of the week, except some increases in screenings, but they are expected.

In Illinois and Indiana every mine not completely closed up for the winter, was in nearly full-time operation by Friday. However, there are a great many mines in all Illinois and Indiana which are not expected to resume unless the winter is abnormally cold. The extreme cold had a retarding effect on coal, even though no snowstorms accompanied it. Friday and Saturday the coal railroads reported their motive power to be reduced about 40 per cent in efficiency. Extreme cold also kept a good many miners at home, operators reported. On Friday and Saturday wire trouble developed all through Illinois and Indiana, so that many a mine was temporarily cut off from headquarters.

St. Louis Trade Is Lively

Cold weather brought business back to its normal stand. The demand is for the middle and cheaper grades principally, with some high grade moving and occasionally a report of anthracite and a little smokeless and a better

volume of coke. Local carload is quiet, but the demand is strong enough to keep the screenings market safe. Country steam is slow, excepting demand for nut from the Northwestern market and some movement of screenings to Chicago.

The Kentucky coal trade is feeling more optimistic, especially as the new year came in with the first seasonable weather of the winter. Over the holiday period production slumped a little, while many industrial consumers got closer

to the bottom of their stocks, but cold weather brought the domestic consumers into the market and started better tonnage movement to the retailer.

Some of the operators, in an effort to force movement of prepared coal, have been quoting jobbers nut and slack only where accompanied with orders for an equal amount of lump, egg or nut, or half the amount where it is block coal. The cold ended that practice. Screenings are scarce and high in price as compared with what they have been for some weeks past. Industrial demand is picking up noticeably and many Elkhorn and Hazard operations that had been down have reopened. Western Kentucky is producing again at a good clip after briefer idle time than was expected during holiday week. Screenings in that field are firm at \$1.25 and mine-run at \$1.40@ \$1.90. Domestic sizes had not ascended at the end of the week.

Northwest Wide Awake Now

Blustery weather with temperatures running down to 25 deg. below zero at the Head-of-the-Lakes and varying below zero all through the Northwest has set the coal trade on edge. Talk of price cutting at Duluth has passed now and bituminous coal is moving inland from the docks at a tremendous rate. A reduction in smokeless at Duluth docks was the only price change recorded. The range now is: Lump, \$9.50; run of mine, \$6.50; screenings, \$5.50. This cut was made in order to gain more smokeless business from the regular anthracite trade. There is some talk once more of a shortage in the most desired sizes of anthracite.

Inquiry for coal for commercial building heating has been most healthy and the independent mining companies on the iron ranges are putting in orders. Many are starting their steam plants for the first time in three years. This is due to the lack of water power. Some of these mining companies will use from 10,000 to 20,000 tons this winter. The railroads are giving especially good dispatch from the docks and the docks are employing extra men to care for the loading rush.

Milwaukee dealers and shippers report a brisk business. The coke trade is correspondingly lively. Pocahontas lump, egg and nut were cut \$1.50 per ton on Jan. 1.

Western Trade Stronger

The winter wave sweeping over the West livened things up a good deal, especially in Colorado. There producers felt a marked improvement in demand for all sizes. The mines of the state were getting a little better than three days running time a week. In Utah general trade conditions improved also, though dealers were not keen to buy until they began to see the bottom of their stocks. Real winter was operating to empty the yards swiftly.

A week of winter around Kansas City with the thermometer registering near zero steadied the price of domestic grades in the Southwest. Mines are working four and five days a week, domestic "no-bills" have been cleaned up, and there no longer is any price shading. "No bills" of steam coal still are reported, but their number has diminished in the last week, in spite of increased production.

Ohio Trade Stimulated

The domestic trade at Columbus was stimulated temporarily last week by colder weather, with the result that retail dealers showed a disposition to come into the market. Some large users of steam grades are inclined to replenish their reserves, railroad demand appears to be better and some roads are taking bids for coal for stocking purposes. It is believed that the approaching end of the present wage contract, on April 1, is having some effect on the trade. During the week ended Dec. 22 the Southern Ohio Coal Exchange reports show an output of 148,232 tons out of a

total capacity of 686,065 tons from 446 mines reporting. "No market" was responsible for a loss of 488,228 tons. Colder weather raised the hopes of the trade at Cincinnati, but it did not affect prices. Screenings in the low-volatile and slack in the high-volatile coals were the features of the market. Mine-run is moving moderately. There is small demand for domestic coals and more than enough supply to go around. Pocahontas lump is now generally \$9. It has ranged as high as \$10.

Pittsburgh had its first real cold snap last week, but it not only failed to affect demand upon the mines but also failed to influence the sellers' position with regard to prices. Householders' supplies are lasting much longer than expected and it would take quite a spell of low temperatures to cause such consumption as would result in much demand for domestic coals. Now that inventory time is past, manufacturers may be slightly freer buyers, but so far there has been no definite evidence of this in the market. Dealers and consumers ridicule the idea of there being a real strike or contest, but admit there may be a voluntary agreement for a short time, to help liquidate consumers' stocks.

New England Shows No Improvement

Notwithstanding colder weather and the slow movement of vessels there is no improvement in the steam coal situation in New England. Buyers show the same lack of interest that was characteristic of the latter part of 1923, and in spite of anxious search the trade is able to find no possible ground for an advance in prices beyond the generally low level that has obtained now for several weeks. The holiday suspension of mining has meant light receipts at all points, but even with minimum tonnages available there has been next to no inquiry for spot coal. Whatever hopefulness may exist for the near future in the industries is confined to certain specialties and is by no means evident to the coal man. Reserves are unusually large. All the storage wharves have a surplus, and in the absence of strike scare there is likely to be only mild request for steam coal during the next month or two.

The dullness at Hampton Roads drags along without interruption. The No. 1 Navy coals are still being quoted at \$4.60@ \$4.75 per gross ton f.o.b. vessel. Sales of cargo lots in this market have become unusual. On cars at Boston there are nominal quotations of \$5.75@ \$6 per gross ton.

The agencies for the higher grade Pennsylvania coals have about abandoned efforts to move tonnage to New England for the present, so large a portion of consuming area there having been restricted by high tariffs on the all-rail route to Pocahontas and New River rehandled at points like New Haven, Providence, Boston and Portland for shipment inland. Until the smokeless coals via Hampton Roads move up in price there will be little doing here for shippers of other coals. High volatiles in the Fairmont district are in the same plight, so far as New England is concerned, and prices are \$1.75 and less per net ton at the mine for mine-run, with almost no sale. It will take something drastic to invigorate the market here for any variety of bituminous.

Seaboard Markets Await Better Demand

The soft coal market along the Atlantic seaboard is waiting for a better demand. Indications point to better

business, but no one seems to be willing or ready to say when it will come. No one appears to be anxious with regard to conditions after April 1. Some consumers are asking about contracts but no big business is reported as closed. The Baltimore market reports an increasing line of inquiry and the supply of coal shipped is larger than the demand. Contracting is taking some attention and it is understood that some good grade of coal, ranging well up with Pool 9, has been contracted for at \$2 per net ton for the early months of the year, but this is below the average, as other contracts for Pool 9 coal are reported as having been placed at \$2.25@ \$2.50.

Colder weather did not stimulate the West Virginia market, and in Alabama the trade is quiet and inquiries are few for either steam or domestic coals.

Foreign Market And Export News

British Coal Output Declines

Some anxiety is shown by British mine owners as to the outcome of the miners' ballot on the question of terminating the present wages agreement.

Production during the week ended Dec. 22 was 5,886,000 tons, a decrease of 70,000 tons when compared with the previous week, but an increase of 157,000 tons over the week ended Dec. 8.

After the recent unusual activity in the Welsh market conditions have become more settled. Most buyers have covered their requirements and efforts are chiefly directed to clearing tonnage so as to avoid delay. Most of the mines are well booked and are holding present prices for delivery during the next few weeks. In some cases concessions have been made so as to effect clearances. The refusal of the tippers to operate a third shift is proving of considerable hindrance to trade and the docks are crowded with steamers waiting their turn to load.

The Newcastle market is on the whole steady though there are irregularities here and there. Best steam coals are going well, present prices being maintained and the operators are asking an advance for January. In some cases stocks are being cleared at reduced prices.

French Coal Market Quiet

A decrease in the production and importation of coal was expected in France during the last few weeks of 1923, on account of the holiday season.

Supplies were, however, sufficient to meet both home and industrial demand and no shortage was feared.

The Nord and Pas-de-Calais collieries definitely decided to postpone until early in January putting into effect the increase of 5 fr. on flaming coals, and to reduce from 10 fr. to 5 fr. per ton the proposed increase on semi-bituminous coals. However, similar increases are already in effect in all other coal fields.

Independent Anthracite Quotations Decline

Lack of demand further affected the anthracite market, and in most sections quotations for independent coals showed a decline from last week. Retail dealers appear to be well stocked and ready to meet immediate needs, while some are soliciting orders. Lower temperatures did not bolster the trade to any extent, while the holiday season which resulted in lower production, was responsible for smaller shipments from the mines. Steam coals continue to be troublesome, with barley in best demand.

There was a sharp decline in the production of beehive coke the last week in December, it amounting to 221,000 net tons, as compared with 256,000 tons during the week ended Dec. 22.

Slight Improvement at Hampton Roads

Very little improvement in the coal situation was noticed at Hampton Roads last week, though prices stiffened slightly. The advance was attributed to lack of supply at the mines rather than to demand, many operations closed for the holidays having manifested reluctance in resuming work in view of low prices.

Coastwise trade and bunkers held their own, while foreign business showed a little life. The Virginian Ry. piers were still behind their schedule, due to the trainmen's strike and lack of coal. Inquiries of shippers were rare and no immediate business of large volume was forecast in the trade.

Shippers made less effort to book cargoes, because of prices that allowed little profit.

Traffic News

Suspend Higher Hard-Coal Rates

The Interstate Commerce Commission has suspended from Jan. 1 to April 30 the operation of certain schedules which purposed to cancel rates on anthracite from Buffalo, Black Rock and Suspension Bridge, N. Y., to Minneapolis, St. Paul and other stations in Minnesota. The proposed schedules provided for a rate of \$6.25 per gross ton instead of \$4.38 between the points named and a rate of \$9.21 instead of \$7.34 from the Pennsylvania mines to Minneapolis and St. Paul.

New Coal Rates in Alabama

The Alabama Public Utility Commission has promulgated an order effective March 1, establishing a new schedule of rates on intrastate movement of coal and coke, which will affect a material saving to consumers of steam and domestic fuel. Only a comparatively small number of increases were shown in the general adjustment. The schedule has been under consideration by the commission for several months and public hearings have been granted both the railroads and the public.

Rate Finding Affirmed

The previous finding of the Interstate Commerce Commission in the matter of rates on coal from the Appalachian District to Spartanburg, S. C., and points beyond, on rehearing has been affirmed.

Suspend New Rates for Scrutiny

In the matter of proposed changes in the rates on coal from Illinois, Indiana, Wisconsin and St. Louis to Iowa, Minnesota, North Dakota and South Dakota, the Interstate Commerce Commission has ordered the new rates suspended until May 1 for investigation.

Monongahela Ry. Adds Tracks

As part of a plan to relieve congestion at its Madsville yards, where a junction is effected with the Morgantown & Wheeling Ry., one of the principal feeders, the Monongahela Ry. has put in commission a four-mile stretch of track extending from the north end of the Madsville yards to Lock 9, which is to be used for second running track service. The company also is putting in thirteen new tracks at Madsville, each a mile long, in order to handle coal and other freight more expeditiously.

As a step toward handling loads and empties to and from the Morgantown & Wheeling Ry., operating on Scott's Run, acquired not long ago by the

Monongahela, that road is pushing construction work on the lower leg of a "Y". When the "Y" is completed loads can be accepted from the M. & W. without blocking traffic while empties are being shunted at the junction point.

"Soo" Coal Traffic Doubles

During the season of 1923 there passed through the Canals at Sault Ste. Marie, Michigan and Ontario, 16,709,305 net tons of soft coal and 1,686,006 net tons of anthracite, as compared with 8,790,571 tons of soft coal and 670,447 tons of hard coal in the season of 1922, according to the report of L. C. Sabin, general superintendent. Shipments during December were 113,600 tons of soft coal and 48,900 tons of hard coal, all of which passed through the United States Canal. Of the season's shipments, 16,547,771 tons of bituminous coal and 1,659,874 tons of hard coal were sent through the United States Canal.

Manley Moves Up

W. J. Manley has been appointed general traffic manager of the Pittsburgh & West Virginia and West Side Belt railroads effective Jan. 2. Mr. Manley has served as general traffic agent of those lines since last October. For three years prior to last October Mr. Manley served as traffic manager of the Logan Coal Operators' Association of West Virginia. Mr. Manley takes to his new position twenty years of practical railroad experience which covers all phases of railroading in the transportation as well as traffic fields, having been raised on the Great Northern, as well as operating a railroad in Peru for a considerable period. For three years Mr. Manley was associated with the Commission on Car Service of the Railway War Board and the Car Service Section of the Railroad Administration at Washington, D. C.

G. E. White Promoted

George E. White was promoted Jan. 1 to be general freight agent of the Chicago, Rock Island & Pacific Ry., headquarters Chicago, Ill., succeeding M. A. Patterson, deceased.

Trade Literature

The Smith & Serrell Co., of Newark, N. J., manufacturers of flexible couplings, have just issued a new bulletin, No. 37, which combines a new catalog describing many of the different types of flexible couplings which this company makes and gives some interesting information on the care and maintenance of couplings, together with engineering data covering the application of each type. A new high-speed coupling for use on high-speed

geared motor and turbine drives also is described, showing the details of construction, method of lubrication and application. Another new product of this company is the pressed steel type coupling for use on fractional horsepower motor drives. One section of the bulletin is devoted to the method of installing equipment with flexible couplings and describes in detail how the machines and couplings should be lined up before put in operation.

The Silent Hoist Co., of 302 McDougall St., Brooklyn, N. Y., manufacturer of hoisting machinery, has just issued Bulletin No. 22, describing the silent hoist electric car puller. This new bulletin describes the method of installing one of these hoists, its simplicity of design, method of drive and capacity.

Obituary

James C. Dennis, manager of the mine forging department of the Pittsburgh Knife & Forge Co., Pittsburgh, Pa., died Dec. 7, 1923.

James Gideon Steel, superintendent of the mines of the Eureka Coal Co. at Birmingham, Ala., died Dec. 23. Mr. Steel was 56 years of age and well known in the Birmingham district.

Martin Allen Patterson, general freight agent of the Chicago, Rock Island & Pacific Ry., with which he was associated for more than forty-two years, died Dec. 18, at Santa Barbara, Calif.

Coming Meetings

Engineers' Society of Western Pennsylvania. Annual meeting Jan. 15, 1924, Blue Room, William Penn Hotel, Pittsburgh, Pa. Secretary, K. F. Treschow, Pittsburgh, Pa.

American Wood Preservers' Association. Annual meeting Jan. 15-17, 1924, Hotel Muehlebach, Kansas City, Mo. Secretary, P. R. Hicks, Chicago, Ill.

Northeast Kentucky Coal Association. Annual meeting Jan. 24, 1924, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

Association Activities

The annual election of the Cincinnati Coal Exchange resulted in E. F. Bardin, of the MacBard Coal Co., being named president; Fred Gore, of the Blue Diamond Coal Sales Co., vice president; John Emslie, of the Crech Fuel Co., secretary, and R. C. Fitzgerald, of the Southern Coal & Coke Co., treasurer. The annual meeting will be held on the last Thursday in January and a nationally prominent speaker will address the members.

The Pennsylvania Coal Mining Institute, of Johnston, Pa., elected the following officers at its regular meeting on Dec. 28: President, W. A. Swift; vice presidents, B. F. Baldwin, Dennis L. Boyle and Thomas J. Davies; secretary, William Fleming, and treasurer, Vincent A. Stanton. Captain Edmund Steidle, of the Carnegie Institute of Technology, delivered an address on "The Occurrence and Detection of Mine Gases." At the meeting to be held Jan. 18 Prof. R. Z. Virgin will make an address.

The Northern West Virginia Coal Operators Association has launched a campaign for new members. In a recent statement John A. Clark, Jr., president of the association, called upon the membership to put forth every effort to have coal companies not members do their share in carrying on the work for the district as a whole. He directed attention to the money expended by the association in defending two cases before the Interstate Commerce Commission and said that the traffic situation is one of a number of critical matters which confront the coal industry of northern West Virginia and that offer opportunity for active co-operation and for constructive ideas and suggestions. It is asserted by President Clark that 50 per cent of the tonnage of the district is now carrying the burden, both financially and otherwise of helping all the operators. If members will endeavor to enroll others, it will lessen their burden, President Clark points out.

News Items From Field and Trade

ALABAMA

Negotiations are under way between Governor Brandon and owners of mines which are now working state and county convicts under the lease system to arrive at an agreement whereby the convicts will be worked under the complete jurisdiction of the convict department. A contract is being sought by which the coal would be mined and delivered at the mouth of the room or the haulageway at a stipulated rate per ton, the convicts to be worked, fed, clothed, guarded and maintained by the state. A large number of state and county convicts are employed in coal mines in the Birmingham district and there has been a strong sentiment worked up for abolition of the lease system in so far as it pertained to coal mining.

In a suit brought by J. L. King against the Kershaw Mining Co. for alleged damage to farming lands from overflow of water from its coal washeries in Walker County, a verdict was rendered in favor of the defendant, the first time a mining company has won a suit of this character in many years.

The Paramount Coal Co. has announced it will soon open two more mines near Helena, making three in all with a producing capacity of about 700 tons a day. The operations will be in a 250-acre tract leased from the Tennessee Coal, Iron & Railroad Co.

ARKANSAS

A new tippie is being erected at the Bernice semi-anthracite mine in Russellville, replacing the one burned in October. Origin of the fire was unknown. The old tippie was said to have been the largest in the Southwest.

COLORADO

A move to eliminate "fly-by-night" coal dealers, who are alleged to specialize on short-weight coal deliveries, by an increase in the annual license for the coal business from \$20 to \$250 was urged by representatives of the larger established Denver coal companies at a recent meeting before members of the City Council.

Production of coal in the state for the first eleven months of 1923 was 9,279,334 tons, according to the report of James Dalrymple, State Coal Mine Inspector. This compares with 8,847,833 tons for the corresponding period of 1922. The average number of men employed in and about the mines was 13,185 and the number of days worked per mine was 141.7.

DELAWARE

A charter has been issued to the Johnson Coal & Briquette Co., of Wilmington, with a capital of \$500,000.

ILLINOIS

A delegation of Carlinville citizens recently called on officials of the Standard Oil Co. of Indiana at Chicago in an effort to get the company to resume operations at its two mines near Carlinville, closed some time ago because of the high cost of production and the fact that coal could be purchased in the open market cheaper than it could be produced. Colonel Robert W. Stewart, chairman of the board of the Standard Oil Co., told the delegation that reopening will depend entirely on market conditions and the cost of producing the coal.

The Illinois Coal Corporation entertained a party of visitors at the company's new big mine at Nason, Saturday, December 29. Albert J. Nason, president; J. D. Zook, vice-president, and Cecil J. Smith, chief engineer of the company, were the hosts. Several of the guests started from Danville Friday morning in the new gasoline propelled railway coach, seating 68 passengers, and rode across the state in it to Mt. Vernon, where it was put in service on the coal company's new railroad, the Jefferson & Southwestern, which runs from Mt. Vernon to Nason and eventually may be continued beyond Nason to make other railroad connections.

Dr. F. C. Honnold, manager of the Honnold Coal Bureau, of Chicago, starts January 15 for a trip to Cuba and the Panama Canal Zone, returning by a United Fruit steamer to Havana with a three-day stop in Costa Rica. Dr. Honnold expects to pause at Key West and also to make a visit at the estate of a friend on the east coast of Florida a short distance above Palm Beach. Mrs. Honnold will accompany him. They will return to Chicago in about six weeks.

The Middle Fork Coal Co. mine of the U. S. Steel Co. at Benton, Ill., has suspended work indefinitely and 800 miners are thrown out of work. Mine drivers struck rather than accept 75c. per day cut in wages. Officials say they can buy coal cheaper than they can produce it.

A total of 850 men were thrown out of work temporarily by a fire which did \$100,000 damage to the tippie at Mine No. 5 of the Centralia Coal Co., Centralia. The origin of the fire is not known but it is believed to have been caused by crossed wires.

INDIANA

The annual report of Cairy Littlejohn, chief mine inspector, shows that during the state fiscal year 25,328,218 tons of coal was mined in Indiana, as follows: Machine-mined block coal, 18,206 tons; pick-mined block coal, 17,164 tons; pick-mined bituminous coal, 14,813,987 tons; pick-mined bituminous coal, 10,514,237 tons. Miners of the major mines of the state received total wages amounting to \$45,920,877.54 during the fiscal year. The total number of employees at the mines was 31,189. Seventy-five fatal accidents in mines averaged one for every 338,181 tons of coal mined. The total number of mining accidents was 6,528. The number of persons killed for each 1,000 employed was 2.40. The miners lost a total of 9,350 days' work because of no sales of fuel, and 7,814 from lack of coal cars. Strikes were responsible for the loss of 459 days of work in the state.

The proposal to consolidate the United Mine Workers' organization of district No. 8, the block coal field, with that of district No. 11, the Indiana bituminous field, was not taken up by the district No. 8 convention at Brazil recently, and officers stated that it was the intention to maintain a separate district organization as long as conditions would justify it. The convention disposed only of routine matters. The district officers were constituted a scale committee and will attend the United Mine Workers' scale conference at Indianapolis in January.

The No. 7 Ayrshire mine, employing more than 100 men, eight miles south of Petersburg, was flooded recently by heavy rains but may be able to resume operations in two weeks.

The Big Four railroad has made Petersburg, a freight terminal. Recently it established its coal terminal there and has built four miles of track just south of Ashby. Coal from the mines in Pike and Gibson counties is taken there where the trains are made up for the north.

The capital stock of the Pike County Coal Corporation, Petersburg, has been increased from \$250,000 to \$550,000.

MARYLAND

The sentences of twenty striking miners, convicted as participants in disorders at Frostburg, involving unlawful assembly, riot and assault, were commuted just before Christmas by Judge Doub at Cumberland, and 15 were released from jail in time to spend Christmas day with their families.

MASSACHUSETTS

In a report filed with the State Legislature the joint special Coal Investigating Committee says that legislation cannot assure a continuous and adequate supply of anthracite, and only by the adoption of

lower-cost fuels which are available can the public solve this problem. The report says that there is no justification for the present retail price of \$16 a ton charged for anthracite by most Boston dealers, and that the price should not exceed \$15.50. The committee recommends federal legislation providing for complete publicity of the accounts of the anthracite industry, including operators and their affiliated sales organizations, and transportation companies and miners' unions; that the President be authorized, in the case of actual or threatened interruption of production, to appoint a special commission of conciliation and inquiry; that the form of contract between operators and miners be revised and penalties provided in case of a breach of either party; that the Interstate Commerce Commission or some other federal agency be given authority, in the event of a fuel emergency, to prevent speculation by wholesalers and jobbers of coal, while in transit from the mines to the consumers, and that the State of Pennsylvania repeal "the now notorious anthracite tonnage tax." The committee urges that Congress authorize some federal agency to standardize the sizes and regulate the quality of anthracite shipped in interstate commerce. It favors the continuance in this state of the special commission on the necessities of life and the emergency fuel act for a period of three years.

NEW JERSEY

Legislation regulating the quality of coal sold in New Jersey is one of the recommendations in the annual report of J. Harry Foley, superintendent of the Department of Weights and Measures. Mr. Foley finds that the laws to protect purchasers as to quantity are adequate, but absence of regulations affecting quality is costly to consumers.

NEW YORK

E. E. Loomis, president of the Lehigh Valley R.R., has sent a letter to stockholders formally announcing a stock offering made possible through the segregation of railroad property and the Lehigh Valley Coal Co., as approved by the U. S. District Court. Under the new plan every stockholder in the railroad company will be granted the right to purchase stock in the coal company at a fixed price of \$1 per share. This privilege, however, will expire next April. Reference also is made to the hearing before the Interstate Commerce Commission on Jan. 17 of the application of the railroad to continue its lease and stock ownership of the Delaware, Susquehanna & Schuylkill R.R.

The Pennsylvania Coal & Coke Co. for November reports surplus earnings of \$11,364 after all charges and ordinary taxes, but before provisions for federal taxes. Surplus for the eleven months ended with November totaled \$738,922 against \$541,629 in the same period last year.

The Walter Engineering Corporation, of 299 Broadway, New York City, announces the affiliation as an associate of Frederick Schwertner, income tax counsel, to handle income tax matters for its clients. Mr. Schwertner is well known as an expert in such matters and has for several years made a specialty of coal-company tax cases.

Stockholders of the United States Distributing Corporation, at a special meeting held in Richmond, Va., approved the recapitalization plan, it has been announced. The plan authorizes an increase in the old 100,000 shares of common stock of \$50 par value and 10,000 shares of managers' stock of \$5 par value to 220,000 shares of no par common and 27,500 shares of 7 per cent \$100 par cumulative preferred stock. The new stock is to be issued to present holders of common on the basis of one share of new common and one-quarter share of preferred for each share of common now owned. The new preferred is to be convertible into common at the rate of four shares of common for one share of preferred at the option of the holder. The preferred stock is entitled to four votes, while the common has one vote.

OHIO

Reductions in the price of hard coal, soft coal and coke ranging from 25c. to \$1.50 a ton in Toledo have been announced by at least one dealer. Other dealers declared prices for soft coal are off from 50c. to \$1 a ton and that a reduction in coke prices is anticipated, but no reduction in hard-coal prices is in prospect, they say.

The Central West Coal Co., of Columbus, recently closed a deal whereby it acquired a tract of 1,000 acres of coal lands with two operating mines at Jasonville, Ind., on the C. M. & St. P. RR. The property has both No. 3 and No. 4 seams of coal and both seams are being operated. The capacity of the two mines is 1,500 tons daily. The purchase was made from the New Calora Coal Co., which name will be used for some time in conducting the business.

PENNSYLVANIA

The officers of the Philadelphia & Reading Coal & Iron Corporation, chartered in Delaware to take over the coal and iron interests of the Reading companies as approved by U. S. District Court Judge Davis, at Philadelphia, are: President, William J. Richards, Pottsville, Pa., who was president of the old Philadelphia & Reading Coal & Iron Co.; Robert J. Montgomery, vice-president; William H. McEwain, vice-president and secretary; David Wilson, treasurer; Martin P. McDermott, assistant secretary, and Charles A. Hurff, assistant treasurer. Directors of the corporation are Joseph B. McCall Newton, H. Fairbanks, William J. Richards, Robert J. Montgomery, William H. McEwain and George C. Coughlin.

The last of the bodies of the five men entombed Dec. 8 in the Mount Jessup mine, at Jessup, were recovered Dec. 31 by rescue workers. The men had been buried under rock. Two of the bodies, one of which was that of Eban Jones, the mine foreman, were recovered about a week after the accident, the third was removed on Dec. 29 and the two remaining bodies on the last day of last year.

H. M. James, formerly electrical engineer for the Hudson Coal Co., is now engaged in consulting, electrical engineering work with offices in the Connell Building, Scranton.

The Lehigh Coal & Navigation Co. is electrifying its No. 9 colliery at Tamaqua, doing away with steam power.

Following the recent fire at the Beaver Valley Coal Co. breaker near Hazleton, the company's board of directors named the following officials to take charge of the plant after Jan. 1: George Reiff, Wilkes-Barre, general manager; George McCay, Wilkes-Barre, general superintendent; William Beltz, of Hazleton, paymaster and purchasing agent.

The Hazlebrook Coal Co., the Stonega Coke & Coal Co. and the Wentz Co. have bought all of the stock of the General Coal Co., a Delaware corporation, and as of Jan. 1, will operate it under their management. The General Coal Co. it was announced will conduct the business formerly transacted by the Wentz Co. and will be the exclusive sales agent for "Admiralty," "Roda" and "Stonega" coal and coke produced by the Stonega Coke & Coal Co., and for the "Dependable" anthracite coal, produced by the Hazlebrook Coal Co.

The Board of Directors, of the Lehigh & Wilkes-Barre Coal Co. has abolished the title of president and general manager effective Jan. 1, and the title of that office will thereafter be president. On the same date, by order of President C. F. Huber, Douglas Bunting, formerly general superintendent, became vice-president and general manager, and Edward Griffith, formerly assistant to the general superintendent, became assistant general manager.

One thousand and seventeen fatal accidents occurred in the mines of Pennsylvania in 1923, according to the annual report of the Bureau of Workmen's Compensation of the State Department of Labor and Industry. In 1922 there were 809 deaths due to mine accidents.

Warren N. McCann, of New York City, has filed a suit in the U. S. District Court at Philadelphia to recover \$771,437 from William M. Richardson, president of the Philadelphia Export Co. McCann, who was a major in the Ordnance Department during the war, alleges in his suit, which is for trespass, that he agreed to sell Tabb & Burtleson, of England, 180,000 tons of coal; that he agreed to buy a large tonnage of coal from the Export company, which in turn was sold to the English firm. It is alleged the defendant addressed a letter to Tabb & Burtleson reiterating representations that McCann had bought coal inferior in quality to that which he had agreed to furnish and that Richardson further solicited business from the English firm, resulting in a cancellation of McCann's contract with Tabb & Burtleson and the Export company obtaining the business that the plaintiff had with the foreign firm. McCann claims

\$571,437 due to the loss of the contract and \$200,000 as damages.

The U. S. District Court at Philadelphia has approved the merger of the Reading Co. and the Philadelphia & Reading Railway Co. sanctioned by the Interstate Commerce Commission, together with the authority to issue bonds and the application of the company to operate its subsidiary railway companies. The company was directed by Judge Davis to file a report thirty days after completion of final steps in the dissolution.

Day and night shifts are working at Port Carbon, on the Schuylkill River, cleaning the river of thousands of tons of culm which have accumulated and caused the stream to overflow its banks. A New York briquet manufacturing firm is negotiating for the establishment of a washery at this point.

RHODE ISLAND

George H. Webb, State Fuel Administrator, and Frederick C. Freeman, vice-president of the Providence Gas Co., declared at a joint meeting of the Providence Engineering Society and the American Society of Mechanical Engineers at Providence recently that Rhode Island will take matters into its own hands and supply its own fuel unless Pennsylvania stops placing restrictions upon the coal industry. Captain Webb said there is more hard coal under the surface of the ground in Rhode Island and Massachusetts than there is in the State of Pennsylvania.

UTAH

There are fifty-four coal-prospecting permits in Utah and the state has a guaranteed revenue in the near future from coal leases on public lands amounting to \$63,225 a year as a minimum. The leases in the state average around 1,000 acres each and the guaranteed production in the four years covering the agreement with the authorities is 1,686,000 tons of coal from thirty-two leases.

VIRGINIA

The Norfolk & Western piers at Lamberts Point broke all its previous dumping records for a day on Dec. 31, when 61,000 tons of coal was dumped.

WEST VIRGINIA

The coal properties of W. E. Deegans in Logan County were sold on Dec. 31 to George M. Jones and Herbert Jones, according to an announcement made by J. Frank Grimet, secretary-treasurer of the various Deegans consolidated companies. The consideration is said to approximate \$1,000,000. The properties transferred are the Cub Fork Coal Co., the Paragon Collieries Co., the Orville Coal Co., the Faulkner Coal Co. and the Paragon Collieries Co. These companies operate seven mines with a total monthly capacity of 75,000 tons. The Logan coal holdings of the Deegans' interests constitute about half of the total holdings of the consolidated Deegans companies. The Deegans interests still have coal operations in the Norfolk & Western territory, in Greenbrier County and in Kentucky.

Although only six resident and one non-resident coal corporations were organized in West Virginia in November, the aggregate capitalization of the companies organized amounted to \$8,120,000. The Sullivan-Pocahontas Coal Co., of Tralee, a consolidation of seven different companies, controlled by J. C. Sullivan, alone is capitalized at \$7,500,000. Other companies organized in November were: the Turner Fuel Co., of Charleston, capitalized at \$25,000; Shamur Coal Co., of Eventon, \$5,000; Laurel Run Coal Co. of Fairmont, \$20,000; Macwarash Coal Co., of South Charleston, \$25,000; Wilbur Fuel Co., of Clarksburg, \$500,000; Mary Martha Coal Mining Co., of Cincinnati, Ohio, \$45,000.

The Putnam Company of Charleston has been organized to develop coal, oil and gas lands at various points in the state, the company having 1,000 shares of capital stock of no par value. Among those principally interested in the new concern are H. H. Carrie, F. L. Thomas, T. Brooke Price, Duke W. Hill and John D. Preston, all of Charleston.

Robert J. Lauder, assistant to the director of the safety department of the Consolidation Coal Co., has resigned his position to accept a position with the Roxana Petroleum Co., of St. Louis, Mo.

J. B. Clifton, of the Raleigh Smokeless Fuel Co., and T. H. Wickham, of Beckley, sailed from New York on Jan. 4 to visit South America in the interest of their company.

Organization of the Clean Eagle Coal Co., with a capital stock of \$200,000 presages operations in the Logan field on a large scale. Among the well-known capitalists interested in the new company are J. Cary Alderson, Naaman Jackson, State Banking Commissioner; Bruce McDonald, L. E. Steele, all of Logan; C. McDonald England, of Lexington, Ky. The office of the company is to be at Logan.

CANADA

Lovell G. Nickles, president of the F. P. Weaver Coal Co., of Montreal, announced on Dec. 5 that he has made application for a charter for the Canadian Welsh Anthracite Co., the purpose of which will be to introduce Welsh anthracite into the Canadian market. Associated with Mr. Nickles will be Sir Alfred Mond and other interests in the Amalgamated Collieries of Wales, and it is the intention of the new company to install a complete breaking plant in Montreal, so as to be able to lay down the Welsh anthracite in Canada in all the sizes required by the Canadian trade. It is understood that the F. P. Weaver Coal Co. will act as agents in Canada for the new company. The Welsh coal interests with whom Mr. Nickles is associated are prepared to ship 100,000 tons of Welsh anthracite to Canada in the first year and to increase shipments as demand warrants.

The Telkwa Collieries, Grand Trunk Pacific Ry., is marketing coal in Prince Rupert. A new seam has been opened.

The coal production of British Columbia for November totaled 200,515 tons, a decrease as compared to the production for the month of October of 27,777 tons. Vancouver Island produced 132,395 tons, which was 10,625 tons less than in October. The Nicola Princeton mines produced 20,842 tons, a decrease of 1,390 tons, and the Crow's Nest Pass district 47,278 tons, a decrease of 15,765 tons.

General Manager Avard, of the Maritime Coal, Railway & Power Co. at Amherst, N. S., has been notified by the Minudie coal miners that the contract offer of his company will not be accepted at present, as the legal adviser of the miners, Mr. Curry, of Glace Bay, is negotiating for the sale of the mine and, pending negotiations, the men do not desire to make any definite agreement.

Alberta Coal Supply Co., Ltd., has been granted an Ontario charter of incorporation to mine and deal in coal and other fuel, with \$40,000 capital. Joseph Montgomery, Harold O. Robinson and Austin Kopas are provisional directors.

Colliery operators, coal dealers, and others were much interested recently by the arrival in British Columbia of a shipment of approximately 400 tons of Welsh coal. It was carried in ballast by a vessel chartered for the Pacific Coast lumber trade. The coal found a ready market at prices a little under quotations on the local product.

G. Howard Ferguson, Premier of Ontario, addressing business men of the City of Edmonton recommended that the Alberta Government open a coal office in the City of Toronto to further promote the sale of Alberta coal products. It was his opinion that for a time at least the business of marketing western Canadian coal in Ontario would have to be handled by the governments of the two provinces.

S. J. Cook chief of the Mining and Metallurgical branch of the Dominion Bureau of Statistics, states that the output of coal from Canadian mines during 1923, determined partly by estimate, amounted to 17,100,000 tons. Alberta had the largest production of any province, the total being 6,884,000 tons, and Nova Scotia was a close second, with 6,784,000 tons. British Columbia's mines contributed 2,825,000 tons, placing that province third among the coal-producing areas. Saskatchewan produced 368,000 tons and New Brunswick 292,000 tons. Approximately 10,000 men were employed in coal mines, three-quarters of them working underground, and one-quarter on the surface. The monthly production per man in October was 49 tons. During the first ten months of the calendar year the total importation of all coal was about 20,000,000 net tons, an increase of about 43 per cent over the preceding three-year average.

New Equipment

Crawler-Tread Loader

That it is capable of cutting a path 20 ft. in width through a pile of material by means of the swiveling feature is the claim made for the new crawler-tread power-swiveling industrial loader recently put on the market by the Link-Belt Co. of Philadelphia. This new industrial loader, shown in the accompanying illustration, is known as the "Grizzly." It is the large capacity, heavy duty loader of the Link-Belt group—a sort of parent to the "Cub" portable belt conveyor.

The new feature of the "Grizzly" loader is the crawler tread, the application of which to the industrial loader is of advantage because of the frequent necessity for moving such loaders over railroad tracks, rough and broken ground, piles of loose material and up inclines. The lower base is of solid, cast-steel construction, which eliminates the numerous rivet and bolt connections and makes for greater durability and rigidity. The lower

PORTABLE LOADER WITH CRAWLER TREAD

The tread of this loader is fitted with a cleaning device which makes clogging impossible under severe ground conditions.

base, which carries the loading mechanism, pivots on the tread in similar fashion to that employed by the larger and more expensive locomotive cranes.

Tread shoes of alloy heat-treated steel, cast in one piece, are attached by a patented design capable of self-cleaning. In the past, it is said, the one fault with mechanisms of this type was their liability to clog with dirt, sand, mud, etc. The Link-Belt self-cleaning tread adapted to the new "Grizzly" is said to make clogging impossible.

One of the principal features of this loader is its ability to swivel and swing independently of the wheel or tread base. It can back into a pile, dig, swivel and elevate at the same time, or it can do any of these operations independently—all at the will of the operator.

The steering mechanism of the crawler tread is controlled by a hand

wheel, all other operations being controlled by levers conveniently located on the operator's platform on the upper swiveling frame.

The capacity of any loader will vary, of course, with the material handled. For the "Grizzly," however, a capacity of 45 cu.ft. per minute is claimed while handling bituminous coal. About the same rate of speed is given for sand and about 40 cu.ft. per minute with 1½ in. and under crushed stone. It is driven by a motor of ample power and of standard design.

Handy, Efficient Cable Splicer

Increased use of coal-cutters drills, cable-reel locomotives and many other portable tools has created a demand for a cable splicer which, aside from being efficient, will not too greatly increase the size of the wire at the splicer. There has long been a need for a splicer which could be applied without solder. Many times the cable breaks somewhere in the mine where solder is not quickly available; then again a soldered joint increases the diameter of the cable.

This small bronze casting clamps onto the ends of the cables to be spliced and firmly grips the strands when given a few blows with a hammer or similar handy tool. The teeth on the inner surface help to hold the cable tightly and form an efficient mechanical and electrical joint. On application, the splicer curls up and binds the cable ends firmly together. This device is a product of the Ohio Brass Co.

CABLE SPLICER

The upper illustration shows the teeth on the inside the splicer. These teeth grip and bind the cable ends as shown in the lower illustration.

Congo Car Mover

The Congo car mover is a device for moving cars at any location on the track. It is manufactured by the Cone-wango Car Co., of Warren, Pa., who assert that a loaded car may be moved a distance of eight inches with a single downward stroke of the handle. The three grips which hold onto the rail are arranged one on each side and one in the rear. These grips operate very efficiently while under load, and yet the operator can slide the device along the rail rapidly, thus moving a loaded car a considerable distance in a short time. A device of this kind is useful around coal tipples at the mines. Owing to the fact that it operates on the downward stroke it is quite possible for an ordinary strong boy to place a car wherever desired. All that is necessary is to set the device well under the wheel and throw the weight of the body on the long lever arm which is provided. All parts are made of steel, thus insuring long life.

MOVING A CAR BY HAND

It is claimed that this lever is arranged to make it readily possible to place a car with much ease and saving of time.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

Volume 25

NEW YORK, JANUARY 17, 1924

Number 3

Quiet Business Boom Responsible for Coal Output Last Year Exceeded but Once in Time of Peace

ABUNDANT transportation and consistent demand characterized the soft-coal industry in 1923. The freedom from car shortage after the first quarter was remarkable in view of the large tonnage produced. The output reached in 1923 has been exceeded but once in a peace year, the total for 1923 of 545,000,000 net tons falling but 23,000,000 tons, or 4 per cent, below booming 1920. It is interesting therefore to compare the 1923 and 1920 records in other respects. Preceding both were large-scale strikes affecting nearly all organized bituminous-coal mines. Consumers' stocks on Jan. 1, 1920, following the six weeks' strike of 1919 were at or just below 20,000,000 tons; on Sept. 1, 1922, following the big strike, stocks were about the same level.

Both strikes were followed by periods of restocking, but with this great difference—in 1920 the railroads were unable to move the coal as it was offered, whereas in 1923 car supply improved from beginning to end. Frenzied bidding and buying of 1920 was replaced by quiet purchasing in 1923. From the beginning to the end of 1920 consumers' stocks were increased by around 27,000,000 tons; in 1923 with no fuss at all, not less than 29,000,000 tons was added to consumers' reserves. With all the frenzy that attended the accumulation of stocks in 1920, there was but 45,000,000 tons on hand at the end of that year. On the other hand, 1923 closed with around 65,000,000 tons in consumers' storage, a new high record for the end of a calendar year. It is anticipated that this figure will be even higher by April 1, 1924.

The fact that at the first of the year stocks had been piled up sufficient to afford on the average a safe supply—that is to say, nearly four weeks' requirements—and that thenceforth throughout the year there was no pressing necessity for coal on the part of any class of consumers or of any locality, was a most important factor in depressing the price. Consumers were willing to take the coal throughout the summer and autumn of 1923, but they were not in dire need and bought as the coal, at constantly lowering price, was forced on them.

It must not be assumed that because soft-coal prices were easy and stocks piled up, general industry was not humming. The consumption of soft coal in this country

in 1923 was about 500,000,000 tons, almost identical in amount with the consumption of 1920. More coal was imported in 1923 than in 1920, but about 17,000,000 tons less was exported, which accounts for the seeming discrepancy. A measure of the industrial activity of 1923, as against 1920, is found in the figures of production of sixty-two commodities as reported by the Census in the Survey of Current Business. The production of these sixty-two commodities, which include coal and coke, was 9 per cent greater in 1923 than in 1920. The Federal Reserve Board reports a 10-per cent increase in manufacturing activity in 1923 over 1920. A few examples serve to indicate the widespread nature of this quiet boom in business and help account for the steady

demand for soft coal. Cotton consumption was 4 per cent greater in 1923 than in 1920, although textiles were considered dead last year. Pig-iron output in 1923 was 12 per cent greater than in 1920; likewise steel ingots, 12 per cent; copper, also 12 per cent; crude petroleum, 16 per cent.

It did not just happen that throughout 1923 the country consistently bought coal, irrespective of immediate requirements. There was definite national planning back of it. The Secretary of Commerce quietly but widely urged storage of coal by all industry. He appealed not once but repeatedly to business interests through their associations to be forehanded on coal purchases, to get supplies early and to forestall the usual autumnal rush and high market. Their response was equally unobtrusive, and were it not for the stock taking records of the government, it would be difficult to realize the extent to which this advice was followed. The railroads sponsored

the program—and have not ceased their efforts even at this date. With less than 7,000,000 tons on hand at the beginning of 1923, the railroads began in June an active campaign for coal storage. On Oct. 1 they had increased their reserves by 10,000,000 tons, or to 17,663,000 tons. They expect to have 20,000,000 tons on hand by April 1, 1924. If they but increase their reserve on wheels to what it was on April 1, 1922, they will have in excess of 22,000,000 tons.

Production of bituminous coal was regular throughout 1923. The best month, January, was 10 per cent

PRODUCTION AND CONSUMPTION

In this diagram the solid bars represent production of bituminous coal by calendar years. The dotted line is consumption. In but two years—1919 and 1922—of the seven from 1917 to 1923 was production less than consumption. In 1917, 1918 and 1923, all years of large production, there were substantial additions to stocks. In 1923, of a production of soft-coal in round numbers of 545,000,000 tons, 495,000,000 tons was consumed, 20,000,000 tons exported and 30,000,000 tons added to consumers' storage piles.

over the average; the worst month, December, was 10 per cent under, with a difference between them of but 9,000,000 tons.

Production of anthracite was at a high level in 1923. Inheriting a shortage from the long strike of 1922, the country was anthracite hungry. Demand was strong as the year opened and after a summer of exceptional output, the trade readily absorbed the output—following

the short strike in September—even at prices enhanced by reason of the wage increase given the miners by Governor Pinchot. Hard-coal production in 1923 was around 95,000,000 net tons, the highest in a peace year. Domestic sizes were the backbone of the trade, for steam sizes were off in price from April on, attendant on the lowering prices of soft coal, with which they were in direct competition in the steam trade.

Price Trend for Year Monotonously Downgrade

SATISFACTORY as was production of bituminous coal, prices were a disappointment. Spot prices ranged downward from an average of \$4.38 per net ton in January, dropping below \$3 in April to \$2.18 in December—that is to say, the market at the end of the year was half what it was at the beginning. There were no corresponding decreases in cost. The average spot price for the year was \$2.77, compared with \$3.67 in 1922 and \$2.55 in 1921.

Spot price, however, is not equivalent to average dollars realized by the operators. In the first place, the two figures are not strictly comparable, for the spot price is what the customer pays and is the operator's selling price enhanced by selling costs or middlemen's margin. In the long run, however, the discrepancy is not great. In boom years the spot price soars well above average realization because a majority of the coal is sold on a conservative basis, usually on contracts. Thus in 1920, when open-market prices for soft coal literally touched the sky, averaging \$5.64 over the year, the average actually received per ton was \$3.75.

But in periods of dull market the spot price descends below the contract price level, as in 1921, when the average spot price was \$2.55 and the average realized was \$2.89. In 1922, because of the shortage caused by the strike, spot prices mounted, averaging \$3.67, but realization was \$3.02 per net ton. The spot price in 1923 started high, as a holdover from 1922, but descended to a low point in December. The average spot price was \$2.77 and it is estimated that the average realized was about \$2.85, a few cents above the open-market quotations.

It cannot be argued therefore that 1923 was a prosperous year for the soft-coal industry. It is particularly significant that, after making allowance for increases in wages alone, the spot price of bituminous coal in 1921 and again in the latter part of 1923 fell below the pre-war record of 1913-1914. Labor cost alone considered, soft coal is now cheaper in the open market than before the war. It is small wonder then that the bituminous-coal industry is not facing 1924 in high spirits.

This unsatisfactory condition is solely due to the overdevelopment of the industry. The war inflation, huge in itself, has since been augmented by the forced development in the non-union fields attendant on the strikes in the union fields in 1919 and 1922. The boom of 1920 also was a contributing factor. The capacity,

both as regards mines and labor, is such that 10,000,000 tons or more per week may be produced and yet the air be filled with complaints of idle mines and idle labor. The year 1923 has given us an excellent measure of the overdevelopment of the soft-coal industry. With a high total production spread almost uniformly over the twelve months, the days of idle time represent surplus capacity.

Distribution of coal was uniformly satisfactory in 1923. There were no hindrances to movement. Every section of the country has had soft coal forced on it.

New England and the Northwest are glutted with fuel. The movement into the Northeast was stimulated by competition between the water shippers from southern West Virginia and the all-rail shippers in central Pennsylvania. Never was so much soft coal—about 32,000,000 net tons—dumped at lower Lake Erie ports for the Northwest trade. Illinois, Indiana and western Kentucky enjoyed an active summer, but entered the autumn and winter with markets stocked and little business. They are now feeling more than any other producing areas the effect of deluged markets.

Except the flare-up in anthracite in September, there was no labor trouble in coal in 1923. The bituminous wage contract signed in August, 1922, expired April 1, 1923, but no real diffi-

culty was encountered in agreeing on a renewal. After some negotiations and considerable jockeying for position, the renewal was made for one year, instead of for two years, as some desired. This brings the expiration on March 31 next. At this writing there is much speculation as to whether a new contract can be agreed upon without a strike. It is useless to attempt a forecast. The miners obviously would in the aggregate profit by a two-year renewal of the present scale, as would the larger, more conservative operators. Another bitter contest such as that of 1922 would shackle the industry with still more development and put even further into the future that day of a more stable industry—if indeed it would not ruin the opportunity and postpone perhaps for a generation the possibility of the deflation so sorely needed.

Those who look only to the present and immediate future see the country overloaded with soft coal and all prospects gone of remunerative prices in 1924. To such there is no remedy save a forced suspension in the union fields—a shot in the arm to bring on the rosy dreams of low stocks, strong demand and high prices. Sentiment against a strike is gaining every day.

The solid bars and the figures in this diagram represent the average realization in dollars per net ton for bituminous coal, as reported by the U. S. Geological Survey, except that for 1923, which is an estimate. The dotted line shows the average spot price as reported by Coal Age.

Loading Machines Appearing in Great Numbers—Types and Principles of Machines and Appurtenances—Interest at Last at Fever Heat—Many Questions Must Be Settled and Problems Solved

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*, Pittsburgh, Pa.

"WHAT is being done on the problem of machine loading?" is the question mining men are asking all over the coal field. The problem is receiving much practical demonstration as well as thought. It is about as commonly discussed as the prohibition question—at the mine, in the office, at meetings and on pullman cars. And it is not something new, as many are led to believe, for loading machines have been an expensive hobby of a few men for many years; only this year has the interest been national. Heretofore, development was intermittent and, at best, pulsating. Someone would conceive ideas of a coal-loading mechanism and then commence to build one.

Too often work would cease before the machine had been completed or soon after it had been given a half-hearted trial. Many machines that had a semblance of practicability failed to make headway chiefly because of lack of funds and of co-

operation from mine owners. Woodsheds, machine shops and garages have been the birthplace of many loading machines. The number of them is legion. How many are there? That is a difficult question to answer, as a veil of secrecy hides the development of many of them.

UNION IMPEDES INTRODUCTION

Progress is slow, as it must be, until sufficient momentum is gathered to sweep the industry. In a way, the move is marking time and will continue to do so, all the while gathering force, till such time as the barrier of opposition thrown up by the United Mine Workers no longer obstructs the introduction of such machines. It is gratifying, however, that practically all the mine owners assert that the day of the loading machine is at hand.

Sooner or later, it is believed, the miners' union will have to yield to economic pressure and agree to a reasonable wage scale for loading machines. With these assurances mechanical - loading devices and methods are developing with increasing rapidity. If the U. S. Coal Commission's reports did nothing

else, its efforts at least caused wider interest in the problem.

Before going any further it might be well to give a definition of a mechanical loader, applying it to the type in most general use. Strictly speaking, a mechanical loader is a machine that performs the greater part of the work of the human loader, one which is devised to transfer coal at the face to mine cars or conveyors, after the face has been cut and shot down, and to do that work with little expenditure of labor other than that required for the manipulation of the machine.

A mechanical loader will never be small enough or flexible enough to match the co-ordination of man's brains and brawn, but it can be made to approximate that ideal. The more nearly it does so the more successful is the machine. Other machines are being built in which the functions of mining coal are added to those of loading. These are known as combination mining and loading machines. Earlier types of these last-mentioned machines were designed to advance entries, but the dual functions of mining and loading are now being incorporated in

The headpiece shows the Oldroyd loading machine, which, unlike other machines, has three conveyors. To the head end of the loading boom is attached a revolving dipper to which are fastened two replaceable strips of steel, which throw the coal onto the lowest of the three conveyors.

JOY LOADING AND DIGGING MACHINE ENTERING ROOM

This machine is employed extensively under all sorts of conditions. Being perhaps the smallest loader in use, it is suited for low as well as high seams. The digging and gathering fingers resemble somewhat the claws of a crab and draw the coal into the conveyor trough.

machines which have as their function the production of coal and not merely the extension of roadways.

The mechanical running of the machines and their performance at work are based upon many principles. Belt or metal conveyors in almost all cases carry the coal from the front end of a machine to a mine car or another conveyor. These generally consist of two units suspended from the body of the machine, which operate independently of each other. For convenience and uniformity of expression in describing various types, the front conveyor is called the loading and the rear conveyor the discharging boom.

On almost all types of loading machines it has been found advantageous to give the discharging boom independently controlled vertical and horizontal movements and to provide only for the elevation or lowering of the loading boom. A few types are provided with a moving device on the head end of the loading boom to facilitate the transference of coal onto the discharging conveyor.

Gears and worms, air and hy-

draulic cylinders, rope drums, shafts and direct connections are the means used to impart motion from motors to the various elements of the machine. The machines travel on tracks, tractors or on the ground in the fashion of a cutting machine. They are made large or small, depending upon the conditions to be met and the whims of the inventors.

COAL COMMISSION'S STUDY

In its report on machine loading the Coal Commission makes reference to two definite machines, evidently of different make, estimating their capacities in eight hours under satisfactory working conditions as 500 tons for the large and 150 tons for the small machine.

It is quite likely that the commission speaking of the big machine refers to the Jones loader, of the Pocahontas Fuel Co., of West Virginia, for the reason that the average output of three machines for a particular shift of eight hours is 352 tons each, despite an actual working time of only 56 per cent. No other machine is known to be in use that has loaded coal at that rate over long

periods. When the commission refers to the little machine as being operated by one man, it must be alluding to the Joy loader. Throughout the report on machine loading, evidence is given that clearly fixes the identity of the two machines.

James Elwood Jones, of the Pocahontas Fuel Co., has for many years been working with a large loading machine in the Pocahontas No. 3 seam. This bed attains a thickness of 10 ft. of clean coal in the mines of this company. Working in thick coal he has demonstrated that loading could be successfully accomplished—even at this early stage of development—by room-and-pillar mining, where conditions are favorable. Because of the excellent results obtained in experiments, Jones loaders are being built at Columbus, Ohio, for use in the mines of this company. These mines are gradually being converted so that the entire coal may be loaded mechanically.

In the main the Jones loader resembles the types of machine in most general use, in that it moves from room to room on track and is arranged with loading and discharging booms suspended from the body of the machine. The loading boom is designed somewhat like the cutter arm of a cutting machine, under which is placed a wide slide pan.

In the chain which operates the loading boom are attached, in place of cutter bits, long arms which slide the coal to the discharging boom. It is a large machine, at present designed to load coal only in wide rooms and high coal. Its crew of twenty-two men attend to all duties relative to the mining, loading and hauling to a sidetrack of 500 tons of coal or more in eight hours. It has a record of loading a 4-ton car in one minute.

In its infancy the Joy loader weighed about 9 tons. The body of the early type was built about a large storage hopper, to which the

MYERS-WHALEY SHOVEL—A HEAVIER MECHANISM OF LARGE CAPACITY

A swinging shovel deposits the coal on the loading boom. The type shown here can be operated in a 4½ ft. seam of coal. It will also load rock, ore, clay or other loose matter with equal facility.

coal was fed by one conveyor and from which coal was discharged into mine cars by another. Believing a loading machine should be small enough to make it extremely flexible and so that one man can operate it, the designer eliminated the impracticable hopper, and reduced its size to that of the present Joy loading and digging machine, which weighs about $3\frac{1}{2}$ tons.

It has but one flight-conveyor pan, which flares out at the head end of the machine and is suspended on a tractor truck so that it may be raised or lowered. The flared-out section of the pan is provided with a pair of digging and gathering fingers which are geared and pinned to describe fixed orbital paths drawing the coal into the conveyor trough. Two hundred of these machines are distributed over Virginia, West Virginia, Indiana, Illinois, Kentucky, Colorado and Pennsylvania.

No better implement than a shovel is known for the hand loading of coal or other loose material. On the Myers-Whaley loading machine, developed fifteen years ago, the principle of a shovel is incorporated. Essentially it consists of a swinging shovel and two conveyors and travels and loads over a 20-ft. front from a mine track.

Both conveyors have lateral movement. The capacity of the shovel with a sufficient car supply is 150 tons per shift, operating in seams $4\frac{1}{2}$ ft. thick or thicker. A number of these machines are in use in coal mines of Pennsylvania, West Virginia, Indiana, Illinois and Colorado, and in rock and ore mines in this country and abroad.

Adoption of the caterpillar tractor

HOLMSTED COAL-LOADING MACHINE, USED AT HARDY COAL CO.'S MINE

In this machine the essential feature is a wedge held in an eccentric path by guides and made to move into the coal and back to the conveyor by a semi-flexible connecting rod from a drive crank.

to impart flexibility of movement in loading at the face and portability in traveling from place to place independently of mine track is a step forward in the development of loading machines. It enables the small loading machine, which does not have sufficient reach for loading from a mine track, to reach all parts of the face, and when thus applied it gives excellent service. George Dillig, of Pittsburgh, Pa., claims priority over all other designers in the use of this device, for in 1920 he mounted an experimental loading machine on caterpillar tractors. That machine loaded out 57 tons of coal in two hours from two rooms in the Hammill mine, near Pittsburgh, Pa.

The Dillig tractor loader as developed today depends upon the powerful action of tractors to ram its nose under the coal to be loaded. This lifts the coal onto a loading boom which deposits it onto a discharging conveyor. The booms are lifted or swung by air jacks. At the present time several of these machines are being built less than 36

in. high for a large company in Pennsylvania. The Valley Camp Coal Co. is preparing to use a Dillig loader in its Kinloch mine, Parnassus, Pa., where plans are made for longwall mining in an isolated panel. The machine will work in the thick Freeport seam, which is topped with a hard roof.

At the Hardy mine of the Hardy Coal Co., of West Virginia, three Holmsted loading machines are in use in room-and-pillar mining. Additional machines for the same place are in process of construction. The outstanding feature of this machine is a reciprocating wedge on the head end of the loading boom, which is thrust under the coal on its forward stroke and drags the coal onto the conveyor on its backward stroke. Reciprocation of the wedge in eccentric guides is accomplished by attaching to a crank a semi-flexible connecting rod. Its general features are similar to those of other loading machines. It will load at the rate of $1\frac{1}{2}$ tons per minute. All the machines already mentioned have been extensively used.

In the Oldroyd coal-loading machine are embodied several of the movements of an arcwall machine in cutting horizontally, as it travels on a track and may be fed straight in toward the center of a face in loading and may be swung also to either rib. The loader breaks the coal down and loads it at the face, and, for this reason, it is heavily constructed. It is equipped with three conveyors supported by two sets of swivel trucks for greater ease in rounding curves.

Coal is fed onto the front conveyor by means of a revolving dipper provided with two steel cutter plates spaced at an angular distance of 180 deg. to each other. The Oldroyd will load at a maximum rate of

DILLIG TRACTOR LOADER—ALSO SUITED TO ROOM-AND-PILLAR MINING

The ram nose of this loader is forced under the coal, which moves onto the conveyor, urged forward by the powerful thrust of caterpillar treads.

2 tons per minute. In one shift it has actually loaded 250 tons of coal in 2.4-ton cars at the Sumner No. 2 mine of the Pittsburgh & Erie Coal Co., Braznell, Pa., where the Pittsburgh seam is 7 ft. or more in thickness. Using a 4-ton wagon, 350 tons of coal could have been loaded out in eight hours.

Other loading machines than those mentioned are in all stages of development. The Wheeling Steel Corporation is developing an air punching heading machine. J. A. Forsythe, master mechanic of the Buckeye Coal Co., is getting ready to build a loading machine at Nema-colin, Pa. Another loading machine is being built at New Florence, Pa. The Jeffrey Manufacturing Co. has started work on a new type of loading machine; one about which little is known is still in the embryo stages of development.

Patrick J. McDonald, of New Cumberland, Pa., has taken out patents on a loading machine that employs the unusual arrangement of multiple-bladed collecting scoops which revolve and thus discharge coal onto a conveyor.

The Vesta Coal Co. and the Bethlehem Mines Corporation are each developing a loading machine. F. N. Wilson, of St. Louis, is constructing a mechanical loading device for the Southern Coal, Coke & Mining Co. It will be known as the "Wilson Chainloader." It has two sickle-shaped arms which, after gathering coal onto a flight conveyor, develop a half twist in two planes and are thus lifted above the loading conveyor. It will load from a mine track and will be built as low as 30 in. The smallest size will weigh

about 4,000 lb. No doubt many other loading machines are being designed or built, but regarding these information is not obtainable.

A few types of shovel loaders, such as the Shoveloder and the Hoar Baby shovel, are giving excellent service in handling rock where roof is brushed in coal mines, but these require more headroom than most seams afford and consequently at most mines cannot be used for loading coal. Their development, nevertheless, has benefited the industry.

There is a fight between two factions, one holding that present plans of mine layout, embodying the principle of rooms and pillars, cannot be changed; and the other, a bit dubious of the stand taken by its conservative opponent, maintains that modifications of longwall mining should be developed to prove or disprove the possibility of adopting the European system in the various seams of this country.

It is surprising the number of sound mining men who are now accepting the advice given many years ago by the longwall advocates, and who are either already experimenting or contemplating the making of experiments into the possibilities of longwall systems of mining. Men in the service of coal companies ranging from the largest to the smallest are members of the latter or minority party. Experiments in modified longwall are being conducted in seams varying in thickness from 3 ft. to that of the Pittsburgh seam. Longwall, by the way, is being tried in this seam.

Without doubt arrangements for loading coal mechanically must be developed, but opportunities for ap-

plying longwall methods, with their inherent cost-saving due to concentrated mining, should certainly not be overlooked. The geology of sedimentary deposits is pretty much the same all over the world, so that what

LOADING RATE, BUFFALO-EAGLE MINE

Shaded areas in diagram show loading rate in tons per hour for a single machine in test made Dec. 13, 1922. Machine with three men to operate it loaded 267 tons in 8 hours. The total operating time was 3½ hours and the rate of loading when in operation was 76.3 tons per hour.

is good for Europeans should, in a measure, be good for us also. However, it must not be forgotten that in Europe longwall is accompanied by backfilling, whereas we propose not to go to that expense. The burning question of machine loading is responsible for the beginning of this revolution. How it will end, only time will tell.

A loading machine has been manufactured expressly for loading from longwall faces. On this machine is a horizontal bar with cutting bits set around its periphery, which revolves so as to throw material in its path up to and on a conveyor that parallels the loading bar. It has several characteristics of the old shortwall cutting machine. It is not portable of itself and consequently in transit must be carried on a truck.

Like the shortwall undercutter also, the machine while loading is moved slowly along the face by ropes and jack pipes. It is said that it can be built to operate in seams as low as 2 ft. thick. This machine will easily load a ton a minute. In a test in a mine of the Buffalo-Eagle Colliery Co., Logan County, West Virginia, this machine loaded 267 tons of coal in 3½ hours of actual working time. The test was conducted by the Allotment Commission of the Chesapeake & Ohio R.R., which, in order to determine what would be a fair proportion of cars to allot a mine having such a machine, had a run made to ascertain its capacity under working conditions. A graphic chart of this performance appears above.

MINE CAR LOADER, DESIGNED SOLELY FOR LONGWALL MINING

This loader consists, in the main, of a horizontal bar covered with bits, which on revolving throws material in the path of a parallel conveyor. It embodies several features of the old-type shortwall cutting machine, moving while loading as the latter moves in cutting.

Major recovery in mining cannot proceed any faster than entry development. For this reason progress in entry-driving machines must parallel that of loading machines. Because most entries are driven narrow, machines for consummating this work have almost invariably been conceived as combination mining-and-loading devices. The Jeffrey heading machine is designed and used for this purpose and makes a remarkable yardage.

It undercuts and shears simultaneously, and as the cutting progresses inward a reciprocating picking frame, the height of which may be adjusted while the machine is in motion, breaks down the coal. The coal falls on a conveyor pan on the bottom of the machine and is conveyed to a mine car in the rear. Entries can be driven to any width by taking successive cuts across the face. It has loaded as much as 30 tons in one hour.

One of these heading machines recently was installed at the Keystone Coal & Coke Co.'s mine, at Keystone, W. Va., on the Norfolk & Western Ry. For the last four months, I am told, it has driven entry at the rate of about 30 ft. in each eight-hour shift, and it has been shown that if it is given cars for continuous loading it will drive over 50 ft. in that period of time. One day when locomotives and cars were available for handling the coal, the machine advanced 53 ft. in seven hours and on several other occasions similar performances were obtained.

The machine will work well under any conditions where the coal is not much below 5 ft. in thickness and where the seam has not an excessive quantity of sulphur or other hard impurities that bits cannot cut. Four of these machines are being used in the Raleigh-Wyoming Coal Co.'s mine, the explosion that recently occurred in those workings

JEFFREY HEADING MACHINE FOR DEVELOPMENT WORK

This machine cuts two vertical kerfs and one horizontal kerf in the coal and then punches out the coal by five strong picks set in a solid frame. It makes three cuts in a wide heading. The rib line with its small offsets can be seen on the right.

being confined to an entirely different section of the mine.

Another combination mining-and-loading machine now being manufactured is known as the McKinlay mining and loading machine. It inherits the principles of the old Stanley header. Briefly, two shafts project from the body of the machine, and to these are secured two arms which revolve somewhat after the fashion of a propeller. These arms are provided with bits that may be located at intervals from 6 to 12 in., depending upon the nature of the coal cut. The relative motion of the two shafts and arms is such as to permit the twin tunnels to overlap each other, cutting a double tunnel 10½ ft. wide.

The sectors between the two circular tunnels are cut by means of a horizontal saw arrangement. The annular rings circumscribed by the cutter bits generally break of their own accord; otherwise revolving wedge wheels tear them out. Barrier plates on the sides of the ma-

chine and buckets on the revolving cutter arms divert the coal into the path of a belt conveyor. This machine will advance at the rate of 3 ft. an hour and is operated by one man.

The difficulty of getting a sufficient and a continuous stream of mine cars to mechanical loaders in rooms is now the biggest drawback to more general use of these machines. This obstacle is being studied seriously by many men. Portable and inexpensive conveyors are thought logical in rooms that may be driven wide in high coal so as to yield a large output per cut. As many as three, and possibly four, cuts might be loaded out of a single room in eight hours. Then a trip of as many mine cars as are required to carry the tonnage from one cut can be spotted and moved at the room neck with little delay. Another remedy suggested is the use of two or more tractor hoppers which ply back and forth, receiving their cargo at the loading machine and dumping it into a trip of waiting mine cars at the neck of the room. This scheme has possibilities.

In November of 1922, before the Kentucky Mining Institute, I suggested the possibility of using a telescopic ladder conveyor of two or more units that might be extended or closed at will by means of racks or some similar arrangement. Interlocking gears could transmit power from one conveyor to another, the conveyors being played out from and supported by crossbars. Such a conveyor could be extended to a sufficient length to permit as many

McKINLAY AUTOMATIC COAL MINING AND LOADING MACHINE

Considering the work it must do, this machine is extremely simple. Revolving cutter arms and horizontal reciprocating saws mine the coal, which is scooped up and deposited in the path of a single belt conveyor by two buckets on each of the revolving cutter arms.

mine cars to run under it as are needed to load out a cut.

J. A. Forsythe, of the Buckeye Coal Co., recently developed a scheme similar in general principle to my proposal. When a loading machine moves into a room it pulls behind it as many as six mine cars, on the top of which are slung conveyor units, one on each car. Each unit is driven by an individual motor and all are tied together electrically by power cables controlled by push-buttons from the loading machine.

Each conveyor rides on a stilt frame, to the legs of which are attached small wheels. An elevated conveyor-frame track lies on the outside of the mine track. In passing over this outer track the conveyors are lifted from the mine cars. In loading, the mine cars are moved from and spotted under the end of the outby conveyor unit.

CONVEYORS CARRIED ON EMPTIES

For transportation purposes a trip of empties is backed under the conveyor units by a gathering locomotive, which is then uncoupled. In backing out of the room the loading machine pushes the conveyor frames from the elevated conveyor track and lowers them to a sling position on top of the mine cars, which move with them. The train is then ready to move to another room, having a supply of mine cars available for immediate use.

What are the possibilities of loading machines in the immediate future? Of first importance in this

connection is an agreement between miner and operator as to a wage scale for mechanical loading. In Illinois the operator is paying the cutting-machine rate to loading-machine operatives. In Indiana the pay of loader operatives runs as high as \$12.50 a day. In neither state has a piece-work rate been made for mechanical loading. However, in Indiana a joint committee of operators and miners was appointed in the spring of 1923 to formulate a scale, but thus far it has not concurred in any recommendation. It is certain that this question will be much to the fore during the coming wage-negotiation meetings scheduled for next month.

It is interesting to note the type of companies that are most absorbed in the development of mechanical loading. Who will derive the most immediate benefit from it? From present indications owners of captive mines are most active in this work. Large commercial coal companies generally are more or less indifferent as to what is transpiring in this new field of endeavor.

CAPTIVE MINES WELL EQUIPPED

Co-ordination of engineering talent in companies that both produce and consume coal is responsible to a large degree for the progressive management of captive mines. As E. W. Davidson points out elsewhere in these pages, captive mines usually are better equipped than those which sell their coal on the open market.

Preparation and sizing of coal re-

quired for various uses is a factor in the progress of machine loading. Steam coal, fired by stokers or pulverized and blown into boiler furnaces, can be loaded by machines which would degrade sized coal too much for domestic and other uses. Slack coal is actually desirable for byproduct coking. If loading machines are developed that are successful, save that they cause regradation of the coal, steel and other industrial companies will not hesitate to adopt them.

Loading machines will help to stabilize the industry by eliminating snowbird and high-cost mines.

Consumption of Natural Gas Up 15 per Cent in 1922

In 1922 there was consumed in the United States 762,546,000,000 cu. ft. of natural gas, having an estimated value of \$84,873,000 at the wells and of \$221,535,000 at points of consumption, according to data compiled by H. Backus and issued through the U. S. Geological Survey. This is 15 per cent more than the quantity consumed in 1921 and 4 per cent less than that consumed in the record year, 1920.

Increased production is recorded for most of the states and in the leading five—West Virginia, Oklahoma, Pennsylvania, Louisiana and California—gains were made ranging between eight and twenty billion cubic feet. There were few changes in rank of the states in production, with the exceptions that Wyoming, with an increased output of more than 50 per cent, attained eighth place, passing Kansas; and that Arkansas, with an increase of more than 100 per cent, went from twelfth to tenth place, passing Kentucky and New York. But in consumption several of the leading states changed relative positions as compared with 1921. Pennsylvania regained first place, having dropped to third in 1921, Ohio changed from first to second, Oklahoma from second to third, California from fifth to fourth, and West Virginia from fourth to fifth.

The interstate movement of natural gas increased from 150,000,000,000 cu. ft. in 1921 to 179,000,000,000 cu. ft. in 1922. West Virginia, which contributed 25 per cent of the total production and consumed only 10 per cent, contributed 66 per cent of the gas that was transported to other states.

During the past few years there has been a considerable increase in the unit value of natural gas, the average value at the points of consumption increasing from 21.6c. per thousand cubic feet in 1919 to 29.1c. in 1922. The average value per thousand cubic feet of the gas used in domestic consumption increased more than 15c. in the past four years and in 1922 was 49.9c.

FRONT VIEW OF JEFFREY HEADING MACHINE, SHOWING PICKS

At the Keystone mine this machine has driven a heading 53 ft. ahead in 7 hours. With a conveyor to carry the coal to a roadway at right angles, or curving away from the machine-driven road, full trips could be loaded with elimination of waits and it is easy to surmise that the tonnage thereby could be greatly increased.

Are "Captive" Mines on the Increase?

Bulk of Opinion Is That "Low-Price Era" Is On and Fewer Steam-Coal Consumers Will Get Mines, but Other Consumer-Owned Tonnage May Grow—
Fourth of National Demand Already Lost to the Market

By E. W. DAVIDSON

WHAT of captive coal?

For a generation bituminous fuel produced by consumer-owned mines has cut a swath in the coal industry of this country—much wider than many men in the coal industry have realized. In 1920 at least one-quarter of the entire bituminous production of the nation was captive. Since then it has undoubtedly increased a little. Probably the percentage fell back during the peculiar year 1923 because of the engulfing flood of cheap coal that finally closed down a number of captive mines; but what will be the trend of this captive coal in the future?

"Downward," promptly replies the great producer of commercial coal. "Yes, probably downward," agrees the railroader. But the industrialist comments thus: "I have an idea it will be somewhat upward because that has been the trend for quite a while. Enough big industries have profited in the long run by owning their own mines so that they will not quit mining after a single doubtful season." And there you are.

The commercial producer—his opinion is a cross-section of several commercial producers' opinions—whose sole business is the mining and selling of coal wherever it will sell, thinks captive coal will recede for several reasons. Metallurgical captive coal no doubt will continue strongly in the hands of its consumers—it is three-quarters in those hands now—but the army of steam-coal consumers will find in the future that the market and not the mine is the most satisfactory place to get fuel.

This will be true, says the commercial operator, because coal is going to be uniformly lower in the future and there will be fewer "emergency" peaks in the market. This will be brought about, he thinks, partly by more reliable and capable transportation and because he dares to think there may be less labor trouble. The seizure of union markets by lower-cost non-union fields, thus reducing union working time, is bound to have an effect, he believes.

With coal entering upon a cheaper

era, he holds, there will seldom recur a time when the steam consumer can afford to run mines. The lessons of the past few months illustrate the point perfectly. Captive mines had to quit because of the low price level of the market. Scores of them ran well into the autumn, loath to shut down and thus break up their organization, even though outside coal at far less than their cost of production pounded at their gates. Finally they could stand the pressure no longer, as in the case of the Standard Oil and Corporation mines in Illinois.

The oil company, with production costs at the mines near Carlinville, Ill., ranging up toward \$2, stood the strain until late November. Then it contracted throughout the Springfield district and Montgomery

County, Illinois, for enough screenings to supply the company's needs to April 1, at prices varying between \$1.05 and \$1.25. There was nothing else to do when other producers were glad to make such contracts. The central Illinois screenings market at the time was from 25c. to 40c. below those prices.

The Steel Corporation's great Middle Fork mine, in southern Illinois, went through about the same experience. It was operated at a loss for months and the corporation wished to keep on operating it, but lack of co-operation on the part of the miners finally exhausted an already sorely tried patience and the mine closed. The sale, soon after, of a wide acreage of Franklin County (Illinois) virgin coal lands,

Relative Spot Prices of Bituminous Coal at the Mines, 1913-1923

This diagram shows the relative prices, not the actual prices, shown in succeeding diagrams in this issue of *Coal Age*, for particular coals. Prices for fourteen coals, representative of nearly 90 per cent of the total output of the United States, were weighted in accordance, first, with respect to the proportions of each of slack, prepared and run-of-mine normally shipped; and, second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the Report on *Prices of Coal and Coke, 1913-1918*, published by the Geological Survey and the War Industries Board. The result is a series of index numbers.

which the steel interests had been holding in reserve, further indicates the attitude of the corporation toward digging its own coal in Illinois.

Then, too, the commercial operator holds the stock argument that the average industrial mine is less efficiently and less economically operated than the mine which depends for its life upon success in the fierce competition of the market. While this is not true in the East, there are many instances where it is true. A string of Midwest captive mines whose extraction is barely 39 per cent—lower by 4 or 5 per cent than that of neighboring commercial mines—is a case in point. The extravagant cost of shaft sinking and development work in another Midwest industrial mine, raising the cost of operation far above that of its neighbors, is another. These things are charged against a carelessness and lack of engineering knowledge that might not be found in a commercial mine.

CAPTIVE MINES MOST PROGRESSIVE

The outstanding fact cannot be overlooked, however, that, as a rule, the captive mine in this country is the leader in progressive mining. The industry behind it ordinarily is better able and often more willing to make heavy investments in good housing, as at Nemaquin, Pa., than the average commercial mine owner. Progressiveness in engineering is well exemplified at the now famous Lynch mines, in eastern Kentucky, in the Frick properties of Pennsylvania and elsewhere. Even the immense commercial mines of southern Illinois cannot outstrip them.

It must be said, however, that progressiveness in engineering often is handicapped by labor in such solidly unionized districts as the states of Illinois and Indiana. The strong effort to introduce underground mechanical loaders is one case in point. Although the unionized Middle West is keen to use them, only twenty-five have ever penetrated Indiana and a bare fourteen in Illinois, whereas there are nearly 100 in West Virginia—52 of them of one make—and only a little less than fifty in Pennsylvania, most of these in the non-union mines of that state. Maneuvers by the operators to get wage scales fixed for loader operators have failed. Down in the unionized Kansas fields the point is equally well illustrated by the fact that,

even after all these years, the union has not yielded to the demand for a cutting machine rate that is satisfactory.

The railroader quoted earlier in this narrative—being a composite railroader and not an individual—believes the wave of captive coal will recede largely because of the future ability of the railroads of the country to perform, and because he feels that sufficient control over coal is certain to be exercised, beginning in the immediate future, so that the days of weird coal prices are about over.

The railroader, like everyone else, can see sound reason why consumers that require a specific kind of coal should continue to own and operate

Complete reports for the year show the largest number of cars on record were loaded during 1923 with revenue freight. The total for the year was 49,814,970 cars. This exceeds by 4,696,498 cars, or 10.4 per cent, the previous record freight traffic, established in 1920. The number of cars loaded in 1923 in excess of 1920 would make a solid train more than 35,500 miles in length.

mines in even larger degree than they do now. But all consumers of steam coal, especially industrial plants, should not feel the mining urge that they had good reason to feel in the past six or seven years. The day of more substantial contracting, he thinks, is coming. When wild fluctuations occur in the market, contracts amount to something less than the well-known scrap of white paper, but he feels that that day will seldom reappear.

Railroads, he thinks, will add few if any mines to those already owned. They will need only enough of their own coal to maintain a balance—say 15 per cent. If anything, the proportion of railroad-owned coal production will drop. In 1920 it was one-third of the whole railroad consumption. Legal restrictions upon railroads dissuade them from further extending properties they may be operating on their own lines.

The average railroader points to the physical recovery of the nation's carriers to support his contention that transportation is sure to be

stronger than it ever was. He points to the fact that during the first eleven months of 1923 a total of 3,704 new locomotives were put in service on American lines as against 2,910 ordered on the best previous year, which was 1916. In 1922 no less than 180,154 freight cars were ordered, about a third of them being coal equipment, and up to Dec. 1, 1923, another 177,845 had gone into service. The American roads put one and a half billion dollars into capital expenditures during 1923, much of which counts heavily toward better movement of freight of all classes.

EQUIPMENT IN GOOD SHAPE

During the active and steadily busy year of 1923 the roads not only increased their motive power and number of cars but got equipment into as good shape for service as it has been in years. Locomotives awaiting heavy repairs Dec. 1 totaled less than 13 per cent, though 15 per cent is normal, and bad-order cars had been reduced to 5 per cent, which is nearly negligible. In spite of car surpluses in some parts of the country during the later months of 1923, which held cars idle, the average per-day car mileage was approximately 30, a year ago is as low as 20.

Such coal roads as the Louisville & Nashville and the C. & O., both chronically handicapped by lack of facilities when coal runs heavily, and the Illinois Central have notably strengthened their positions by adding trackage and terminal space that will count directly for the benefit of coal movement, not to speak of their additional power and cars. Most other roads serving coal fields have made special efforts to increase their coal-moving facilities, which, with the general improvement of receiving lines, practically guarantees excellent transportation of coal, for the immediate future at least.

Turning back to the ideas of the industrialist—another composite character—who thinks captive coal mining will increase somewhat, we are invited to contemplate Henry Ford. That genius of gasoline has built a vertical trust which requires the inclusion of coal as one of the raw materials. There are other vertical trusts, the industrialist says, that will go into coal just as Ford has. That will be one big source of expansion for captive coal.

Of course Ford faces market problems which he has not yet solved and

which possibly every other such enterprise will have to face. He has a surplus of production over his own needs. Per ton costs mount steeply when mines do not operate regularly. So Mr. Ford, on occasion, has forced coal at prices above the market onto unwilling buyers who sell him automobile parts. That helps to keep up his running time and to keep down his costs. But it is radical marketing and there is no assurance that he or anybody else operating captive mines will always find themselves able to unload by the same expedient.

This sort of thing will count heavily against captive mines in times of low market, but the industrialist's answer is that many vertical trusts of the future may be able to hold their coal productive capacity down to about the level of their own consumption and thereby escape the difficulty of disposing of surpluses.

He does not realize, however, as does the veteran coal producer, that lump coal must bring lump prices at any mine, lest the property's revenue fail to meet the costs of operation. The mine that crushes all of its lump deprives itself of a good earner.

The industrialist points also to the public utility as a probable wider owner of coal mines. The great public utilities, consumers of both steam and gas coals, have long been in the coal fields. Notable among them is the West Penn Power Co., with its Springdale coal operations close to Pittsburgh, Pa., all controlled by the American Water Works & Electric Co., Inc. Another example is the Insull interests, owning the Commonwealth Edison Co., of Chicago, and controlling the Northern Illinois Public Service Co., the Central Illinois Public Service Co. and other big power groups throughout the Middle West. The coal consumption of such utilities as these runs into millions of tons annually, supplied by such mining companies as the new Industrial Coal Co., with two Franklin County (Illinois) mines: the Utilities Coal Corporation, operating mines in Central Illinois, Harlan County, Kentucky, and Logan County, West Virginia, and other mining properties operated principally by the Peabody Coal Co., of Chicago.

One other source of additional operators of captive mines which the industrialist thinks about are the owners of commercial coke plants. He is not thinking of coal coked directly by the steel interests but of byproduct corporations. The By-

Anthracite Prices for Eleven Years

This diagram shows in dollars per gross ton the average company circular prices and average spot quotations on "independent" stove and buckwheat sizes of Pennsylvania anthracite at the mines. Prices shown are averages of the range as quoted on the New York market.

Products Coke Corporation, of Chicago, capable of carbonizing 1,500,000 tons of coal in one plant at Chicago, now draws coal from the Solvay Collieries Co.'s mines in West Virginia and the Black Mountain Corporation mine in Eastern Kentucky. Other standard coking companies attached to the Solvay or Koppers interests also are increasing their consumption of coal and low-temperature distillation could very well add a long line of coking plants all over the country which the industrialist pictures as divided into ownership groups that will want to operate coal mines. He is counting on an adjustment of railway freight tariffs to permit the coking of coal on through rates.

So much for what is visioned for the future. What exact information is there on captive coal of the past? Unfortunately, the body of information is not exact but approximate data compiled by and for the U. S. Coal Commission is illuminating.

One of the outstanding facts about the captive mine is that it averages far better running time than the ordinary commercial mine and somewhat better time than even the best of commercial operations. The accompanying table showing operating time of consumer-owned mines compared with commercial mines for both 1920 and 1921 is enlightening.

Quoting from the U. S. Coal Commission report on "Relief from Irregular Operation and Overdevelopment": "Consumption of bituminous coal was abnormally low in 1921. The soft-coal mines of the country worked an average of 149 days, or about half time. Consumer-owned mines quite generally averaged well above commercial mines. The regular connection and the interest of the consumers in maintaining regular output at their mines thus gave these mines better operating time in a year when lack of market was the controlling factor in the operation of all soft-coal properties."

"The production of iron and steel was at low ebb in 1921 and the mines connected with that industry made a correspondingly poor record. But the railroad-owned mines and those controlled by public utilities and industrials operated well above the average. Second only to the captive mines in regularity of operation were those owned by large, well-established commercial operators. Thus in Pennsylvania a group of 159 captive mines average 185 days, compared with 176 for the large commercial coal operations, 135 for all others and 151, the average for the state. Captive mines in Kentucky average 85 days more work than large commercial operations and 91 days more than the small mines.

"The record of the large commercial operators in Ohio is better than any other group because they are shippers of Lake coal. The large commercial operators in Virginia and Ohio worked more days than the captive mines in either Pennsylvania, West Virginia, Illinois and Indiana. The best records in 1921 were made by public-utility-owned mines in Pennsylvania and West Virginia."

How much advantage in cost of production has the captive mine? From the table of comparative working time of captive and commercial mines in the seven states for 1921 it can be computed that the average number of days worked that year by captives was 179.5 or an average of 14.95 days per month, compared to only 147.7 or 12.3 days per month, by the commercials.

A Coal Commission curve based on 1921 data from 119 mines scattered over the country shows exactly how the percentage of cost per ton rises in proportion to the loss of working time. It assumes 25 days a month to be full working time and takes that as its 100-per cent base. According to it, production costs at a mine working 15 days a month are 13 per cent above the base, and at a mine working between 12 and 13 days a month costs would mount 20 per cent above the base. By such cal-

culations the captive mine has an average of 7 per cent advantage over the commercial mine.

This 7 per cent looms large when applied to the output of, say, a million-ton captive mine and a million-ton commercial mine. The average spot price of soft coal for 1921 was \$2.55. If an average mine cost were assumed to be \$2 for the captive mine, its entire output for the year would total \$2,000,000, as compared to \$2,140,000 for the commercial mine, or a margin of \$140,000 in favor of the captive.

INTERESTING CAPTIVE-MINE DATA

In 1920, according to a study made by C. G. Duncan from data partly estimated and otherwise open to revision, captive mines in this country produced 139,148,000 tons of soft coal, or 24.6 per cent of the country's total. They contributed 22.2 per cent of the total shipments of raw coal and 61.9 per cent of the total that was made into beehive coke at the mines.

Steel companies are shown to be by all odds the largest holders of captive mines. The output of mines affiliated with the steel industry totaled 75,232,000 tons for that year. This is about three-quarters of the entire coal consumption of the industry.

Railroad-owned mines that year produced 46,705,000 tons, which was about 8 per cent of the national total and approximately 30 per cent of the total coal consumed by railroads. Industrial consumers of various other classes owned mines that year which produced about 8,500,000 tons, or 12 per cent of the amount of coal used by industrial plants other than those of the steel industry.

Geographical distribution of captive-mine tonnage shows that the heaviest captive production is by the Connellsville region of Pennsylvania—the great coking field serving the steel industry—Alabama, Illinois and the Far West. Consumer holdings in the Connellsville region are so extensive that they produced in

1920 about 31 per cent of the entire Pennsylvania output. In Alabama the captive-mine output was 46 per cent of that from the whole state, and in Illinois, 27 per cent. More than half the Far Western coal is mined by railroads and metallurgical companies. In Washington, Montana and New Mexico the proportion is about two-thirds, in Utah more than 50 per cent, in Wyoming 40 per cent and in Colorado about 38 per cent.

Production by the steel-company mines for years has kept pace almost exactly with the increase in total production of soft coal in the nation. Captive coal has increased also under the ownership of manufacturers of brick and other refractories, glass, paper, oil, cement and chemicals. Almost every industry with a coal consumption of 200,000 tons a year either owns mines now or has owned them in the past; but it is a notable fact that a number have taken fliers in coal only to let go at the first opportunity. This was true recently of a Pennsylvania cement concern which bought a West Virginia mine only to quit it for the open market.

Many a wise coal observer foresees that a good many of the smaller industries that now dig captive coal will soon quit the game. The prophecy for low priced steam coal during the next few years certainly is a discouraging one for any steam-coal consumer who thinks of getting into coal operation. The indications are that the prophecy will, in general, be borne out. Then it remains to be seen whether a shrinking proportion of captive steam coal will be counterbalanced by an expanding proportion of gas and special coal before the industry can determine which way captive coal is bending its course.

Commercial producers, who already see more than 25 per cent of the whole coal demand of the country taken out of the market by captive mines, today are counting on good rail service, less labor trouble and fewer future market peaks to preserve for them the remaining 70 to 75 per cent of the trade of the nation.

Captive Mines Work When Commercials Cannot*

* This table, compiled by the U. S. Coal Commission, shows the average days worked in 1920 and 1921 by groups of consumer-owned mines in seven states, compared with days worked by mines depending on the market. The advantage to captive coal rolls up a considerable margin against commercial coal. The average for 1921 is 7 per cent lower cost at captive mines.

Engineering Achievements Outstanding Features Of Mining Progress in 1923

Organization of Engineering Forces—Greater Use of Mechanical and Electrical Horsepower—Increased Application of Automatic Equipment—Higher Efficiencies in Material Handling

BY EDGAR J. GEALY

Associate Editor, *Coal Age*

EVERY year impresses more forcibly on the coal industry the paramount importance of mechanical and electrical engineering and equipment as factors in production. More and more the mine approaches the ideal of a large machine operated by power generated at the mine mouth or at some distant station and controlled by push buttons and switches from the surface. We are a long way from such an ideal, and doubtless will never wholly attain it, especially in some mines and at the mine face, but time, patience and effort will bring it appreciably nearer.

In earlier years the engineer was largely a man who obtained by machinery a certain given result—at what cost of energy was regarded as a minor consideration; the wonder was that the result could be accomplished with any expenditure of power. Nowadays engineers are going over the equipment and finding where power is being wasted. Many engineers are engaged not so much because of their ability to construct plants and indeed to run them but because they are able to save money in their operation.

Operators are beginning to realize that having the machinery that will do the work as and whenever they want it done is not enough. Devices or systems are needed that will enable the work to be accomplished not merely effectually but economically. This kind of service differentiates the mere engine runner and electrician from the mechanical and electrical engineer.

As the engineer has come into his own he has made many changes and much progress in the handling of his work. Engineering staffs have materially increased, more technical men skilled in engineering theory are found in the organizations. The work of the staffs has been systematized. Records, data, charts and tabulations tell the story of each machine.

Following the example of the

power-plant industry, more efficient and reliable meters and recording equipment have been developed and applied, so that the engineer is able to ascertain definitely what any new arrangement, equipment or device will save him and can base his action not so much on his judgment or his preference as upon definite findings which will enable him to state just what can be saved by any given change in methods or equipment.

The modern engineer keeps data on the machinery he has replaced. He obtains photographs of the old and new installations. His operating records tell him what he can do under new conditions, duplicating those he has formerly controlled, and also prove the success of his plans after he has put them into effect. These methodical ways of planning and conducting his work have not only contributed to the efficient performance of his labors but have been the means of promoting confidence in his ability to economize and in consequence have enabled him to obtain the necessary funds for more elaborate systems of operation and control.

AUTOMATICITY SPREADS

During the year just past the use of automatic equipment and devices was greatly extended. Control apparatus were perfected and applied for the purpose of eliminating the difficulties that accompany manual operation. It is true, few radical changes were made in either design or construction, but the number of applications of electricity to mining was greatly increased.

By changes in design higher efficiencies were attained in many types of machinery, and corresponding advances made in the control apparatus to be used with it. These changes in detail in each instance may not have been great, but owing to the number of machines in use in the mining field the aggregate advance is of great potential economic value.

This year's developments in haul-

age equipment have consisted of greater refinement in mechanical and electrical detail. The outstanding features have been better tracking qualities, improved spring suspensions, greater battery efficiencies and such improvements in control as have resulted in lowered power losses.

Dynamic braking has been more generally applied. Locomotives of 25- to 30-ton capacity have been equipped with contactor control, ventilating fans and air brakes. By the use of ball and roller bearings mine cars when made up into larger trains than usual have been handled with ease. In many cases by these changes the need for large and for more locomotives thereby has been obviated. In fact, heavier loads than heretofore have been handled with smaller locomotives and hoist motors, thus effecting savings in power-generating equipment and power costs.

Almost everywhere the comparative figures available show that the friction load of anti-friction bearing cars is about one-fourth that of cars with ordinary sleeve bearings. Many records show even better results and point to great possibilities of further advance in the new year.

Last year equipment was designed for the largest coal hoist in the world, the drive consisting of two 2,000-hp. motors. Aside from the more extended use of hoisting equipment of small and extremely large size the most important progress in hoists has been in the application of accurate control and of dynamic braking.

Under several conditions heretofore considered practically impossible for efficient electrical control, hoisting systems have been developed that are capable of handling various loads at extremely low and high speeds with a minimum expenditure of power and without special complicated control. At the present time one coal company is seriously considering the develop-

ment of a complete automatic hoisting and dumping installation controlled by the footman at the level from which the cars are being hoisted.

The H. C. Frick Coke Co. is installing a belt conveyor over four miles long for transporting coal from the mine workings to the shipping station. It consists of twenty sections, each driven by induction motors varying in size from 50 to 75 hp. All are of the wound-rotor type. Solenoid brakes are provided for stopping and holding the conveyor belts when the power is cut off from the motors.

The control is so arranged that the motors start in sequence, beginning always at the delivery end, so that no coal can be delivered by a moving belt onto one that is standing. As each motor reaches full speed it trips a switch which energizes the starting circuit of the next succeeding motor. If any motor stops, it automatically stops all the motors preceding it in the conveyor system but allows those following it to run and clear the belts of any coal in transit.

In the pumping field this year we have seen the perfected development of the primed, started and controlled centrifugal pumping station. This complete equipment obviates the necessity for an attendant. So complete is the automatic control that it will work not only when the pump is in normal operation but under circumstances which would be likely to cause a breakdown. The pump begins to operate as soon as the water in the sump has risen to a predetermined height and automatically stops when the water has fallen to a level similarly predetermined.

For small gathering pumps a valve has been developed which automatically opens when the water in the sump reaches a height sufficient for pumping and closes when the water recedes to a point where pumping should stop. With this device a single pump may be arranged to unwater several areas by means of an octopus suction system.

An important development of the year which will greatly affect fan drives was the building of an alternating-current brush-shifting motor with shunt motor characteristics. This machine gives adjustable speed without auxiliary apparatus and permits large savings of power during the night and in idle periods when the fan may be slowed down. This motor is designed to run normally

at a low speed. It fills a long-felt need for an adjustable-speed alternating-current motor that will be simple and the speed of which will be virtually independent of its load.

Such rapid strides have been made in power-plant generation that today it is a relatively simple matter to obtain a kilowatt-hour of electrical energy from the consumption of two or two and a half pounds of coal. With the further development of the mercury boiler and turbine it is highly probable that some of the best power plants under favorable load conditions will be able to generate a kilowatt-hour of energy per pound of coal.

Where water conditions are favorable many large coal-mine power plants are operating at very low costs. These plants have an advan-

The engineer is no longer regarded as a spender but as a saver of money, and many notable improvements in power costs have been made, with increases in efficiency, during the last year.

tage over those in other industries, for the fuel they use is sometimes that which is cleaned from the roads and as it must be gathered to keep the tracks clear its cost to the mine power plant often is only the charge for conveying it to the power house. In many plants the small sizes are used which are inevitably made in the production of marketable coal. In this instance also the power-plant charge for the fuel is only the cost of preparing and conveying it to the furnaces.

The automatic substation has continued in popular favor, as is evidenced by a growing tendency to make the converting station automatic and thus obtain a reliable power supply for direct-current equipment. New features added to this equipment have broadened its field of application and made for greater reliability.

More converting stations have been placed inside the mines where they can be closer to the load and deliver better voltage with less power loss. Where the seams are thin and the mining progresses rapidly there is a growing need for portable power-converting substations, large companies having many

important mines finding it more and more necessary to have such equipment for emergency service. As the application of electrical machinery increases the demand becomes greater for a flexible power system. Ease of operation, control and repair has definitely favored the installation of the motor generator over the rotary converter.

Large power-consuming apparatus in the mine is now being fed through heavy high-voltage cables. Alternating current has been more extensively carried into the mines, voltages as high as 2,300 and 4,000 volts now being common. Feeder cables have been removed from the usual wet and dangerous hoisting shafts, and where the water is highly acidulous are now being installed in separate boreholes lined with iron or even terra-cotta pipe.

Marked improvement has been effected in the operation of portable machinery such as coal cutters, loaders, room hoists and cable-reel locomotives, thanks to the use of all-rubber insulated portable cables. In many operations where the ordinary portable cable would be dangerous and economically impossible all-rubber cables have proved their worth and established their practicability.

The mining field has been given special consideration by the electrical manufacturers, who have more fully recognized the hard service mining equipment must withstand. Special insulation and winding impregnation is now given to such motors and control equipment as are to be used in the mine. By this process it is easier to prevent moisture from causing delays.

Anti-friction ball and roller bearings have been adopted for many types of motors, thus effecting higher efficiencies and eliminating serious delays and damage that result when acid water, dust, dirt, sand, etc., enter the bearings.

The Fynn-Weichsel induction motor, capable of correcting lagging power-factor and operating at high power-factor on loads which must be motored higher than the average load condition would require, opens up big opportunities for correcting the low power-factor loads usually found around coal mines.

With these achievements in the past year and with indications of further expansion and application markedly discernible we are entering the new year confident that it will show even greater progress than those which have preceded it.

Marked Increase in Tidewater Coal Business Does Not Reflect Natural Growth

Gain of 9,000,000 Tons in Dumpings at Atlantic Ports Represents Emergency Requirements Both at Home and Abroad—Ruhr Controversy Brings Short-Lived Boom in Export Trade

BY J. S. BURROWS

Of Castner, Curran & Bullitt, Inc., New York

THIRTY-SEVEN million net tons of bituminous coal was dumped at the five Atlantic Ports in 1923. This total shows a substantial increase of nine million tons over 1922 but does not reflect any natural growth when compared with the preceding years since the war. In other words, there is no new business that has come to tidewater shippers in recent years other than emergency requirements at home as well as abroad.

On coastwise business the ports are in keen competition with each other for the existing business, while all new markets abroad are closed to American coal by high freight rates and unfavorable money exchange.

RAIL RATES HAMPER EXPORT TRADE

Fuel oil has been such a tremendous factor in restricting the use of tidewater coal all along the Atlantic seaboard that the only room left for expansion is in the export trade. Those engaged in trying to sell export coal are convinced that the strongest barrier in the way today is the high rail rates to tidewater ports and they believe that if rail rates on coal for export could be reduced by 40 to 50 per cent, sufficient export business would result to compensate the railroads through the greater volume of tonnage handled.

In the year just closed, export business showed an improvement over 1922, which year, however, showed the lowest tonnage in many years. This business came—mainly to Baltimore and Hampton Roads—in the "emergency" occasioned by the early developments in the Ruhr controversy. The new business remained throughout the summer months and departed as suddenly as it had come, when the "emergency" was past and the purchasers were able to re-establish their regular connections abroad.

About 5,000,000 tons was exported overseas in 1923 as compared with 1,600,000 in 1922, and nearly 22,000,-

000 in the banner year of 1920, when it was thought that a strong foundation had been laid beneath our export prospects and that a considerable part of the tonnage obtained

that year would continue. The bunker business, at the ports under consideration, accounted for a dumping of nearly 5,500,000 tons last year. This was nearly 25 per cent more

DISTRIBUTION OF COAL DUMPED AT NEW YORK

DISTRIBUTION OF COAL DUMPED AT PHILADELPHIA

DISTRIBUTION OF COAL DUMPED AT BALTIMORE

DISTRIBUTION OF COAL DUMPED AT HAMPTON ROADS

than in the previous year and may be regarded as a normal tonnage in this direction.

The coal trade felt the competition of oil first in the bunker business and over a period of years has seen one great liner after another convert to oil, with the result that the mainstay of the bunker business today is the tramp ship and older boats engaged mainly in freighting. Consequently the tonnage varies from year to year in accordance with the trend of the general export and import business of the country and to a very large extent depends upon the relative price of coal and oil, as many ship owners do not hesitate to change from one fuel to the other under favorable conditions.

Tidewater business usually is thought of in terms of the New England market and it is true, of course, especially with a light export demand, that New England is the objective of the tidewater shipper. Many of the largest consumers in New England now burn oil exclusively and in the late months of 1922 and the early part of 1923 other plants stocked up heavily with British coal, which they found satisfactory. New England in general, however, was much in need of adequate stocks of coal following the bituminous strike and throughout all of 1923 took in sufficient coal to build up reserves and provide a goodly margin of safety for the future.

13,000,000 TONS TO NEW ENGLAND

Thirteen million tons, or 35 per cent of the total tidewater tonnage, was loaded into vessels for New England destinations. Hampton Roads enjoyed the bulk of this business, 55 per cent of the dumpings of the three Hampton Roads piers being for New England account. As compared with former years New England tonnage in 1923 exceeded both 1921 and 1922. The other divisions of tidewater statistics, namely "Inside Capes" and "other tonnage" vary but slightly from year to year and may be compared in the accompanying tables.

With respect to the position of the five ports, they show about the same percentages of the total business in 1923 as in 1921. Owing to the strike in 1922, New York, Philadelphia and Baltimore, being most affected, slipped back as coal-loading ports while Hampton Roads dumped 58 per cent of the total business, but with the restoration of normal conditions in the mines the affected ports returned to their customary positions,

although it will be seen that Baltimore made a considerable gain in the past year over 1921.

Prices at loading ports throughout the year have been governed entirely

by supply and demand. At the beginning of the year there was a general shortage of railway equipment and a strong demand for coal, so that the highest prices were obtained

in the early months. As railway service improved and coal became more plentiful at the piers, prices steadily declined from month to month until coal could be bought in the late autumn and early winter at a price below the cost of production. As a result, many mines which ship to tidewater have closed down.

At the beginning of the new year the tidewater shipper is confronted with heavy stocks of coal in New

England and along the coast, and with continued inroads of oil fuel everywhere in his accustomed markets at home he realizes that he must turn to new territory. This means export markets, and if he cannot enter these markets at even present below-cost prices, some help will have to come from the other end of the coal business—the railroad people—in the form of lowered transportation charges on export coal.

No Adjustment of Northwest Freight Rates Despite Hullabaloo

Flood of Complaints Anent Alleged Inequalities Brings About Only Trifling Changes—Examiner's Report Favors Docks Over Rail Shippers—Protest Delays Effective Order

A GREAT hullabaloo about freight rates offered some serious diversion from the business of competing for markets in the Northwest in 1923. No adjustments were made during the year however. The docks made a struggle to get either a reduction of their own rates inland or an increase in competing rail rates. Following the filing of a complaint with the Interstate Commerce Commission for such relief, all the other factions interested in Northwest trade hurried to file counter complaints so that the Commission consolidated five of them and heard them together in six busy days beginning May 2.

The first complaint was I.C.C. Docket 14,476, by the Northwest Dock Operators' Association, attacking past adjustments of rates from Illinois (more particularly from southern Illinois, whose competition was most keenly felt) to points in Iowa, Minnesota and the Dakotas as being unreasonable. The rate on lump is \$3.47 and on fine coal \$3.29. The second complaint was I.C.C. Docket 14,622, by the South Dakota Board of Railroad Commissioners, seeking lower rates on South Dakota fine coal into various regions. The third was I.C.C. Docket 14,533, by the Sioux City (Ia.) Chamber of Commerce, asking lower rates to that city both from Duluth and from Illinois. The fourth was I.C.C. Docket 14,477, by the C. Reiss Coal Co., asking, for the benefit of the Lake Michigan docks, that the Holmes and Hallowell scale be applied to Illinois coal meeting Michigan dock coal within the State of Michigan. The fifth was I.C.C. Docket 14,142, in which Illinois, through the

Illinois Traffic Bureau, asked for the adjustment of inequalities in rates to local stations from Lake Michigan docks and from northern Illinois.

The dock operators, in their attack on Illinois rates to the Northwest, pointed out that since 1917 the commission had increased rail-lake-rail coal rates \$1.74 while increasing Illinois and Indiana rates only \$1.17 to the same territory. It was their principal argument. Wayne Ellis, the new secretary of the dock association, surprised the rail men with the brevity of his argument, which consisted mainly of placing in the commission's hands a mass of records supporting a case based upon the theory of rate making adopted by the commission in its own decision on cement rates. The main Illinois contention was that the rates in existence are so high now as not to give Illinois producers an equal chance at Northwestern markets.

Dock interests said they hoped for a change in rates to be made before the end of the 1923 season, record breaking though such speed would be. As a matter of fact an examiner's report was filed in the autumn recommending in effect that very little change should be made in the rate fabric as between Northwestern docks and Illinois and as between Lake Michigan docks and inland points, but it was greeted only by protests from all hands, which were formally filed. Up to the end of 1923 no further definite action had been taken by the commission. All sorts of pressure was exerted by North Dakota to obtain a more favorable rate for its lignite, but that, too, remains in abeyance.

In general, the docks interests

were favored over rail shippers in Examiner C. I. Kephart's report, filed Aug. 3, but which has been protested and has not been ordered into effect. The recommendations begin with one that would reduce rates on coal going off the Lake Superior docks 10c. a ton on short distances up to 35 miles, and ranging down to 1c. on distances up to 350 miles. Rates from Lake Superior docks to certain points in northern Iowa would be reduced 17 and 18c. Rates from both docks and Illinois to Sioux City would be reduced in varying amounts from 22 to 36c.

Rates from Lake Michigan docks to points in South Dakota would be reduced amounts ranging from 38c. at Chamberlain to \$2 at Rapid City. The relation between rates from the various Lake Michigan docks into Wisconsin would not be disturbed. The Commissioner found, however, that the rates from southern Illinois and Lake Michigan docks to Wisconsin points are unduly prejudicial to dock shippers and preferential to shippers in southern Illinois in small accounts.

Another diversion was the assault which the Federal Trade Commission made upon the Northwest Dock Operators' Association. Late in April this commission formally cited the association for conspiracy to suppress competition and create a monopoly in the sale of anthracite and bituminous coal at wholesale and retail in the Northwestern territory. The complaint alleged both violation of the Federal Trade Commission Act by reason of unfair competition and the Clayton Act by price discrimination.

The charges included these: Comparing price lists and agreeing upon them before making them public; blacklisting retailers; selling coal in the Twin Cities, which is keenly competitive territory, at prices less than those charged for the same coal in Duluth; undercutting competitors to force them to join the association; compelling purchasers to use their coal only for purposes outlined in the contract; declining to take certain municipal business so that local retailers might have it; refusing to sell coal to dealers not possessing the usual yard equipment.

The dock association, of course, denied undue price fixing, efforts to restrain trade and create a monopoly and everything else illegal. The case dragged along through the late summer and autumn with no decision by the end of the year.

Spot Coal Prices for 18 Years: What They Reveal

Violent Fluctuations of Post-War Days in Striking Contrast with Preceding Decade—Business Prosperity and Depression Reflected—Car Shortages, Strikes and Threats of Suspension in Evidence

BY F. G. TRYON AND W. F. MCKENNEY*

READERS of *Coal Age* have learned to use and to value the index of spot prices of bituminous coal developed by the present editor of the paper. The principal landmarks of the curve of spot price appearing weekly in the market review—the sudden rise in 1916, the peak of early 1917, the plateau that marks the Fuel Administration's maximum price, the extraordinary peak of 1920, the depression of 1921, and the secondary peak of the strike year 1922—all these are familiar to students of the coal trade.

In fact, to a great many people—perhaps to the average citizen—these violent fluctuations in price, particularly the peaks of 1917, 1920 and 1922, typify the whole coal industry. Consumers are inclined to judge the industry by what has happened since 1916, ignoring the decade of uneventful history before. To do so, however, may give quite a misleading impression both as to the stability of the industry and the profits of the owners, and also as to the outlook for changes in price.

It is, therefore, of more than merely curious interest to trace the course of spot prices into the pre-war days, which we still think of as "normal," whatever that may mean. A recent study made by the Geological Survey, in co-operation with the President's Conference on Unemployment, has pieced together the best available information and carried the record of monthly spot prices back to 1906. The results are shown in diagram 1.

The diagram reveals at once an extraordinary difference in the course of prices before and after 1916. It is not merely that the war has raised prices to an entirely new level—a new tableland, as it were, the low points of which are practically twice as high as the old level—the notable thing is rather that the shape of the curve has changed. The extraordinary peaks and valleys of the post-war curve are conspicuously absent in the years preceding 1916.

That the coal market was subjected to the play of disturbing factors in those days is indicated by the notations in the upper part of the diagram, which explain the ups and downs of the curve. The alternating prosperity and depression of the business cycle affected spot prices then as now, but not, perhaps, in the same degree. Thus the financial panic of late 1907 was shortly reflected in a decline in the price of coal, and the price remained relatively depressed during the dull year

increase, as will be seen from the curve, but the increase, which reached a maximum in the early autumn of 1907, did not exceed 20c. a ton, an amount that would hardly be noticed in such a car shortage as occurred in 1917 or 1920.

Strikes occurred in the pre-war period, and they left their mark on the spot price. Suspension, or the threat of a suspension, caused a peak in the price in the early part of the "even" years 1906, 1910 and 1912. Here again the increase in price looks negligible alongside the increase, let us say, of 1922. Yet some of these pre-war suspensions were formidable demonstrations of the strength of the union. Thus in 1906, 44 per cent of the bituminous miners were out on strike. The total number of man days lost was 13,000,000, and in some districts the men were out for three months.

Again in 1910, the mines in Illinois and the Southwest Interstate region were closed practically five months, yet the increase in average spot price was only 19c. a ton over the year preceding. The sharpest little peak of the pre-war period occurred in early 1912, when the usual threat of a suspension of bituminous mining was reinforced by a stoppage in the anthracite region and by a sudden demand at tidewater, associated with a strike of the British miners. Even this combination of causes produced an increase in the average price for the country of but 60c. a ton over the year preceding, an increase which disappeared within two months.

Why was it, it may be asked, that the same kinds of causes which have produced the violent explosions in prices since the war—failures of labor supply, of transportation, or of both—produced such comparatively slight effects before the war? The answer is: (1) That strikes closed a smaller percentage of the total capacity of the country then than now; and (2) that the reserve power of the railroads to make up for a shortage of coal when it arose was greater then than now. Whereas a general strike order in 1919 could

Monthly Average Spot Price of Bituminous Coal, F.o.b. Mines, 1906 to 1912

These figures have been compiled as nearly as the records permit in the same way as C. E. Leshner's average spot price of bituminous coal, first published in the U. S. Geological Survey's "Prices of Coal and Coke, 1913-1918," and since carried forward in *Coal Age*. They represent average of trade journal quotations for twelve coals representing the great bulk of the production, weighted first with respect to the proportions each of slack, prepared, and run-of-mine normally shipped, and second with respect to the tonnage of each normally produced. Data subject to revision.

1908 and the opening months of 1909, to recover in the autumn of that year with the revival of business. Much the same change in spot price accompanied the financial depression which began in the closing months of 1913 and continued through 1914 and the first half of 1915. But the changes accompanying these depressions amounted to only a few cents a ton between high and low changes that seem insignificant alongside of the contrast between the boom of 1920 and the slump of 1921.

Nor were car shortages wanting in those days, though it is clear that they were less frequent and less acute than now. In the business boom of late 1906 and 1907 occurred a rather notable congestion of the railroads, which caused much comment at the time. The spot price did

*Published by permission of the Director, U. S. Geological Survey.

and did close 72 per cent of the capacity of the bituminous mines, a general strike in 1913 would have closed but 59 per cent of the capacity. Moreover, in the pre-war suspensions, it seldom happened that the entire membership of the union was called out. Usually some of the organized districts outside the Central Competitive Field stayed at work. With the supplies of non-union coal relatively greater than now, and with the railroads able to make up more speedily a deficit in coal supply when the strike was over, the increase in price attending these general suspensions was singularly small.

The data used in plotting diagram 1 for the period 1913 to 1923, are C. E. Leshner's "Average Spot Price on Fourteen Coals," weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each coal normally produced. The figures for 1906 to 1912 here shown have been assembled as near as possible in the same way. Quotations from the *Black Diamond*, the *Coal Trade Journal* and other sources have been pieced together and averaged with the same weights used by Mr. Leshner for the later years.

For twelve of the fourteen coals in the *Coal Age* Index it was possible to obtain quotations back to

1906 from one source or another. For two of the coals used by Mr. Leshner, the present writers could find no quotations; these two are eastern and western Kentucky. An attempt was made to procure records of spot prices actually received by large producing companies that were in business throughout this period, but no company was found that could make accurate separation of its spot and contract sales realizations for the period in question. The quotations become less and less satisfactory as the reader goes back into the earlier trade journals, and no journal seems to have made it a regular practice to report prices until about 1905. Naturally the accuracy of quotations for a given market varied with the care and skill of the correspondent in that market, and not all the quotations appeared trustworthy.

The coals selected for the group of twelve were the ones which appeared to be most accurately quoted, yet even here there apparently are discrepancies revealed by comparison of the quotations for one coal with others, and a considerable number of omissions. Where necessary interpolation was made in order to complete the string of quotations. Because of these possibilities of error, the figures are subject to revision, but it is not likely that they will be seriously changed.

The curve for the country as a whole, is, of course, a composite of local conditions that may vary widely. To throw light on these local differences we have charted typical coals from the Middle West, the district shipping to the Lakes, and the districts serving tidewater. These diagrams (2, 3 and 4) are drawn to a larger scale in order to bring out more clearly the fluctuations in price, and they show what was happening to spot prices from 1906 up to the latter half of 1916, when the war boom sent prices soaring upward beyond the limits of the scale here used. The diagrams are arranged one above the other, so that changes for one group of coals can be compared with those for another during the same period.

The curves represent weighted averages of the quotations for run-of-mine, prepared sizes and screenings, the weight used being the relative proportions of these sizes shipped in 1917.

The two Midwestern coals—Carterville and Franklin and Clinton—both quoted in the Chicago market, are dominated by the biennial suspension. They reached their highest point in 1910, when Clinton was quoted in one month at something over \$2 a ton. The suspension of 1910 centered in the Mississippi valley, and the Eastern fields—Ohio and Pennsylvania—resumed opera-

Diagram 1—Monthly Average Spot Prices of Bituminous Coal, F.o.b. Mines

The course of coal prices shown in this diagram is an epitome of coal for 18 years.

tions fairly early. Therefore, while these high prices were recorded for Indiana and Illinois coals, shippers from the Hocking and Kanawha fields reported a relatively small advance in price. Even quotations for

smokeless-coal on the Chicago market did not rise any higher than \$1.31 f.o.b. mine for run-of-mine. In fact the Hocking and Kanawha prices are the steadiest of those showing great disturbance only in

1906 and 1907—the first year because of the suspension which closed union mines in the East, the second year, apparently because of the traffic jam connected with the boom times of that period.

Diagram 4 represents two smokeless coals. The quotations for Pocahontas and New River up to 1912 inclusive represent prices in the Chicago market. Thereafter they represent the price in the Boston market. The quotations for Somerset are partly for the New York market and partly for Boston. The fact that the Pocahontas quotations represent prices for inland delivery and the Somerset quotations prices for tidewater delivery, explains in part the discordances between the two curves in the years 1906 to 1912.

The price of Pocahontas should be the most sensitive of all the coals, because the demand for it is so diversified, and because it participates in both the tidewater and the interior trade. Careful study of the Pocahontas curve does show that it responds more quickly than any of the others to changes in the general tone of business and that it registers both the periodic strikes of the interior and the changes of the tidewater market. The sharpest peak in the smokeless prices, it will be noticed, occurs in March, 1912. It is a composite of three disturbing factors, (1) the regular biennial suspension anticipated for the bituminous fields; (2) the stoppage of anthracite mining at the expiration of the anthracite wage agreement; and (3) and perhaps most important, a strike of the British miners, which created a sudden vacuum in supplies of bunker coal at our North Atlantic ports.

These prices are of course spot, or open market, quotations and they do not reflect the amount of profit received by the operator. They are weighted down by the volume of contract business which continues to move as usual at customary prices. That the ups and downs of the spot market had relatively little effect on the average receipts of the substantial companies is shown by the figures of average sales realization on both spot and contract business which follow:

Average Sales Realization on all Bituminous Coal Produced, 1906-1922

(As reported to the U. S. Geological Survey)

1906.....	\$1.11	1912.....	\$1.15	1918.....	\$2.58
1907.....	1.14	1913.....	1.18	1919.....	2.49
1908.....	1.12	1914.....	1.17	1920.....	3.75

1911.....	1.11	1917.....	2.26		

Diagrams 2, 3, 4—Pre-War Variations in the Spot Prices of Bituminous Coal

The six coals for which price fluctuations for eleven pre-war years are shown in these diagrams are representative of the three largest soft-coal areas—the Middle West, the Eastern high-volatile and Eastern low-volatile fields. By comparing one with another, it will be noticed how little the Illinois strike of 1910 affected the Eastern coals, but how the boom in smokeless coal prices in 1912, following the British strike of that year, was reflected in the West. At the end of 1916 the prices of all these coals hit the sky and went beyond the scales on these diagrams.

Coal Freight-Rate Decisions Made and Pending Point Path to Normality

In Disposing of Complaints This Year Interstate Commerce Commission Probably Will Pass on Rate Structure of Most of the Country—Relationships Between Origin Districts Most at Issue

BY WAYNE P. ELLIS

IF THE history of soft-coal production in 1923 spells "nothing else but," it has forcefully confirmed the oft-repeated statement of the operator that, given transportation service of 100 per cent at the mines, the normal competitive forces of supply and demand will set at rest most of the ills of the coal industry. But, without straying further into conjecture, many facts indicate that that elusive bird called "normal" has had the adaged sprinkling of salt on its tail and should soon be in captivity. One of the indications is the large number of decisions rendered and complaints pending before the Interstate Commerce Commission involving freight rates on coal. When these complaints are finally disposed of, as may be expected by the end of 1924, that body will have passed upon the present coal-rate structure of the country, with the possible exception of the Far West and the Southeast.

The complaints now pending have to do for the most part with relationships between origin districts. They are an indicator of normality because they show that the coal-shipping and consuming public, which took without much open discussion all that was put on its head in the way of increased freight rates during and since the war, is now relieving itself of pentup grievances.

Freight rates on coal are now about 75 per cent above the levels on Jan. 1, 1917. Prior to that date there had been little change for fifteen years. In the pre-war period the soft-coal business of the country developed under a general freight-rate structure of established fixed differentials between grouped points of origin to grouped points of destination. By reason of the method by which the general advances in rates were applied to coal, the rates from these coal fields in closer proximity to the consuming markets were advanced a larger percentage than the more distant fields. The question before the Interstate Commerce Commission is broadly

whether or not the larger percentage advances from the short-haul fields should be reduced or the smaller percentage advances from the long-haul fields should be increased.

Many arguments have been advanced by the contending parties on both sides. These contentions have been set forth so well in the decision of the Interstate Commerce Commission in what is known as the Ohio-Michigan Coal Cases (reported in 80 I. C. C. Reports, page 663) and the decision is so important as bearing upon the thought of the commission in disposing of similar complaints now before it, that the following brief résumé of that portion of the decision bearing upon the issue of relationship is offered.

On that phase the commission was not called upon to decide the reasonableness of the rates, as there was no such allegation in the complaint. It was necessary, however, for it to determine, under the express terms of the Transportation Act of 1920, the effect of any change in the situation upon carrier revenues, and decide upon a basis that would not impair railroad earnings. As the decision states, "Stripped of surplusage, the naked issue presented by the pleadings and evidence is this: Have the increases made since the original decision disturbed the relationship under the differential there prescribed so as to bring about undue prejudice to complainant and

undue preference of the Crescent Coal fields?"

The original decision referred to was in the case known as Bituminous Coal to C. F. A. Territory (I. & S. Docket 774, reported in 46 I. C. C. Reports, page 66), in which the differential from the Pittsburgh, Connellsville Fairmont, southern West Virginia and eastern Kentucky high-volatile coal fields—that is, the Inner Crescent group—over Ohio districts to affected territory was ordered to be increased from 25c. per ton to 40c. per ton. Affected territory may be generally described as comprising northwestern Ohio, northern Indiana (excluding the Chicago district) and the Lower Peninsula of Michigan. The same territory is covered in the order of the commission in the Ohio-Michigan cases.

The commission's decision summed up the evidence of the complainant (the Southern Ohio Coal Exchange) in two propositions, as follows: "(a) That the differentials here in issue were fixed when the rates were substantially lower than at present, that the relationship has been destroyed by the various increases since made, and that under existing rates greater differentials in favor of southern Ohio should be established to restore the proper relationship; and (b) that southern Ohio is entitled to greater differential because of its proximity to consuming points in central territory."

Before taking up these proposi-

(a) These rates did not actually become effective as the 15c. per ton advance authorized in all coal rates by the Interstate Commerce Commission was added at the same time, making the actual rates 158, 198 and 217 respectively.

tions, and in order to portray the situation more effectively, the accompanying table is given containing the average rates in effect to thirteen representative points in affected territory from the three general origin groups.

Under proposition (a), the complainant requested the Interstate Commerce Commission to establish the rates shown in column 5 in the table. These proposed rates were arrived at by using the rates approved in docket I. & S. 774 from Ohio (the average is shown in column 3) as a basis; adding to such base 15c. under Ex Parte 57 (The 15 Per Cent Case), 30c. under General Order 28, and 40 per cent under Ex-Parte 74 (Increased Rates, 1920). The method produces the average rate of 263 from Ohio, as shown in column 5 in the table, which is approximately 184 per cent of the base. The proposed rates from the Inner and Outer Crescent were then arrived at by increasing the rates shown in column 3 by 84 per cent, the same as the Ohio rate. Column 7 shows what these proposed average rates would have been after the 10 per cent general reduction in rates on July 1, 1922.

The principal reason given by the complainant for approval of these proposed rates was the fact that increased operating costs had brought about the general increases in rates since 1917, and contended that the manner in which the increases were applied "cast a greater portion of the burden of the increased costs on the coal traffic from Ohio than on that from the Crescents."

The commission rejected this contention; first, because it had, in a number of cases previously decided, refused to change coal-rate differentials on that ground; and second, because fixed differentials on coal are the rule and "stabilize rate relationships between competing producing points or markets," which is important in a "highly competitive commodity like coal."

From a careful reading of the

decision, it must be concluded that the commission arrived at the opinion that the differentials should be widened because of proposition (b). The decision states that "upon this record we are of the opinion that the southern Ohio districts are not now enjoying the full advantage of their location with respect to the markets in affected territory." Distance (plus perhaps other handicaps of lesser importance) appears to have been the principal factor considered by the commission in arriving at the conclusion to increase the differential.

No finding was made as to rates to non-affected territory. The opinion states that the carriers would "be expected to make such readjustment of their rates to that territory as may be necessary to bring them into harmony with the readjustment of rates" required to affected territory. As a result the carriers have made readjustments to part of the non-affected territory.

Two significant factors should be noted in connection with this decision: (1) that the commission reiterates its belief in the justice of the group principle of making coal rates; (2) that while all eleven commissioners agreed that the differential should be increased, five of them believed it should have been made larger.

Whatever significance may be attached to the decision in the Ohio-

Michigan cases affecting the differentials between the Ohio and Crescent fields as indicating what action the commission may take in similar cases now pending before it, it must be borne in mind that each case will be decided on its merit on the record that is made in each case and in accordance with the particular circumstances and conditions which surround the movement of coal from the districts involved. The long-haul districts took heart after the decision of the commission in the Illinois coal cases, 1920, wherein they ordered the restoration of the 70c. differential between northern and southern Illinois. In the Ohio-Michigan cases it has made a different decision, but in each case it must be concluded that the commission arrived at its opinion from the facts as made of record.

It cannot, therefore, be prophesied what action will be taken by the commission in particular cases involving the same factors as was presented to it in the Ohio-Michigan case on the question of relationship or differentials between the fields.

Empties Thirty-five Cars At One Time

A rotary car dump just installed at the Colonial No. 3 Mine, of the H. C. Frick Coke Co., is 400 ft. long and dumps a trip of thirty-five cars at one time. It is more than twice as large as any other equipment of this type heretofore built. It is similar in construction to the 26-car dump built for the Snowden Coke Co., at Brownsville, Pa., but that is only 120 ft. long. The net load of coal discharged every time the car dumper turns over will be from 130 to 150 tons. The weight of the empty cars will be approximately 50 per cent of this load, or 60 tons. The car dump itself weighs about 150 tons, making a total weight of 360 tons. The constructors are the Car-Dumper & Equipment Co.

MARKET REVIEWS

Markets and Production in 1923 and Forecasts by Our Correspondents in Leading Coal Fields—Diagrams and Tables of Spot Prices of Coal and Operating Records of Producing Districts

"Battle of the Century" Is Fought in Northwest With Big Flow of Coal

Lake Traffic Gets About 32,000,000 Tons During 1923, Which Exceeds Boom Year, 1918, by Nearly 3,000,000 Tons—Throat-Cutting Competition Runs Through Season

THE battle of the century" was fought all over the Northwest during 1923. Dock armies and rail armies marched and countermarched back and forth and up and down Minnesota, Wisconsin, Iowa and the Dakotas, fighting for the complacent coal trade of those states. In the dock forces there were armies within armies. In the rail forces there were all sorts of separate and detached maneuvers. And outside of the regular forces of both there were guerilla actions galore.

As a result of the whole campaign the Northwest got cheaper coal than it has had for years. It got all it wanted and a good deal more. The fighting for the privilege of supplying this coal was so bitter that coal traders' margins narrowed down to little or nothing. At the end of the year the various armies were almost in a state of collapse from forced fighting on empty stomachs while the consumers of the Northwest were literally stuffed with good coal and the docks were loaded to the rims.

Never before had there been a Lake movement of 32,000,000 tons. The biggest previous season of Lake coal shipping was 1918, with 29,388,000 tons. The month of November alone was the greatest November bar one. In November, 1922, the wild rush to get post-strike coal to a famishing Northwest took a total of 4,008,000 tons off the Lake Erie dumping points and sent it up-Lake. In 1921, which was not the worst year in history, the month's total was barely 1,500,000 tons. But in November, 1923, the total reached 3,735,000 tons!

A few more statistics as of Dec. 1, 1923, show that the season up to that date was about 72 per cent ahead of 1922 and approximately 44 per cent ahead of the season of 1921. Navigation, which had opened May 1, closed officially on Dec. 12, when insurance rates went off, but a good deal of coal reached the north docks in those twelve days, and in the mild weather which followed in the next few days a few more dribbles of fuel tied up alongside, waiting for a chance to unload.

The heaviest receipts of coal yet recorded at the Head of the Lakes in any one year were unloaded at Duluth in 1923, according to the final official figures of receipts given out by the United States' Engineer's office. The official figures in net tons are as follows: Anthracite, 1,419,984; Bituminous coal, 11,268,337; total, 12,688,321. The next largest year was in 1918, when 11,390,913 tons was unloaded. The total increase received in 1923 over the average for the previous six years is 35 per cent

or 3,316,749 tons. The season extended from May 5 to Dec. 10. The total number of cargoes was 1,441. Largest day's receipts was on May 5 when 28 cargoes aggregating 266,686 tons, were received.

Receipts by vessel at Milwaukee did not exceed those of 1918, as did the receipts of most lake ports. However, plenty of coal reached the docks of that city. Vessels brought 3,233,122 tons, the largest volume since 1918, when 3,446,000 tons arrived. Most other upper Lake docks had received more than in any other year, by the time vessel movement came to an end.

But the battle for markets did not end then. There could be no ar-

mistice in such a war. Blood had been shed, so to speak, in great volume all season, rules of fighting had early been scrapped and there was no insurance to go off Dec. 12 for salesmen, or any other hindrance to the tooth-and-nail struggle to sell. Movement off the docks was considerably reduced during December, as was movement into the Northwest by rail, indicating that the country was sated for the time being, but coal in abundance was easily at hand ready for delivery.

The facts are, the dock operators, figuring on a countrywide strike in the union fields next April, are stocked with cheap coal and ready to profit by it. It is estimated there will be 6,000,000 tons of Eastern bituminous on the docks April 1. This carry-over, the biggest ever, much of it sewed up at the ridiculously low prices of the late summer and autumn, may enable the docks to recoup all the losses so many of them suffered in the price-cutting campaign they ran all through the autumn against themselves and against Illinois, Indiana and Kentucky rail shippers. At Duluth-Superior alone on Dec. 1 there were free stocks totaling 5,875,000 tons of bituminous coal. Other docks were equally well stocked.

Just how the docks and rails

divided the Northwestern market during the year is difficult to say. The battle line wavered back and forth often and widely between the rail coal assaulting from the south and the Lake coal counter-attacking from the north and east, with a flank turning movement executed every now and then by Dakota lignite from the west. That particular lignite doubled in production over average previous years, so the total of it in the market was approximately 3,000,000 tons.

Illinois and Indiana shippers vary in their estimates of the volume of coal from those states that went into the Northwestern trade, but the consensus is that the total is about the same as in recent years. The realization, however, is much less. It has been so much less, in fact, that a few of the Midwestern producers most fortunately situated as to outlet into sections other than the Northwest largely withdrew from the territory, centering their attention upon regions where competition was less ruinous.

The price of Illinois and Indiana coal going north ranged far downward from even so low a level as that of 1921, when industrial stagnation kept the country's total coal

on this coal—including, from spring to winter, all sizes from screenings to 6-in. lump—ran from \$2.32 to \$2.75 and in 1921 from \$2.70 to \$3.05. Of course, there were wide variations from this, in many special instances, but the record of that one mine is typical of the average experience of the whole southern Illinois field.

Early in the summer, as the navigation season opened, strong efforts were made to maintain prices of Eastern coal going into the Lake trade, but the net result was failure. A good deal of coal shipped on open price contracts was the first development. Then general undercutting started, resulting in splits among dock interests before the trade generally resigned itself to price levels at which coal-at-cost from Illinois, taking a \$3.47 rate into the Northwest, could be met.

Docks at no time were moving coal into the interior as speedily as they had hoped, but a good indication of how the season wound up is shown by the figures for shipment off the Head-of-the-Lakes docks for November. In that month 23,699 cars were loaded off as compared with 23,436 the month before and with 20,638 in November of 1922, when the grand post-strike rush was on.

As the year finished, the Northwest was showing no great coal hunger. Soft coal moved on a price basis only and even anthracite was a trifle sluggish, for retailers had taken as much of it as was customary, and December was not severe. Everyone in the region looked forward to winter months in which they could obtain all the coal they wanted, whenever they wanted it, and worried not at all about April 1 and a strike.

For once the Northwest had little cause to worry about its anthracite supply. While it did not get as much

hard coal as in some previous years it received a sufficient supply from first to last in spite of the brief tie-up due to the miners' strike which Mr. Pinchot so obligingly settled by increasing the price of coal. This increase is the only thing about anthracite which seriously harassed the Northwest. Hard-coal shipments arrived with fair regularity during the bulk of the season except September, causing no flurry whatever except a small and largely artificial one near the end of the year, when it became noised abroad through the towns of Duluth and Superior that the hinterland had sewed up all the hard coal there was while the lake-edge communities snoozed.

The demand for stove and egg sizes got too heavy for the docks to handle during November, and there was some parcelling out of coal in

small lots, and insistence upon the buyer taking a certain proportion of chestnut and pea sizes, all of which had a tendency to fret the trade a little, but at no time was anybody frantically fighting for fuel. The increased price did some good for the briquet manufacturers and aided the Pocahontas business materially, however.

Duluth's total receipts of hard coal for the year were approximately 1,500,000 tons while another 300,000 tons went to other Lake Superior ports. Milwaukee received 971,824 tons of hard coal at about its regular rate all season by vessel, except in the low month of September, when only 32,000 tons arrived, and, in addition, got approximately 150,000 tons by car ferry. Thus gently did a year of little labor trouble and practically no transportation disability treat the Northwest in its regular business of getting anthracite.

SPOT PRICES F.O.B. MINES ON CHICAGO MARKET OF BITUMINOUS COAL FROM FOURTH AND FIFTH VEINS, INDIANA

New England Bituminous Trade in 1923

Hampton Roads Shippers Dominate Market Greater Part of Year—Too Much Coal and Collapse of Prices—Forecast for 1924 Complicated by Wage Negotiation

By G. G. WOLKINS

BUYING power collapsed so early in 1923 that for the bituminous-coal industry it proved a highly unsatisfactory year. Renewal of the wage agreement prior to April checked any tendency toward lower production cost in the union districts, and except for a few weeks in the spring the outlet in New England for central Pennsylvania grades was pretty much restricted to the narrow strip west of the Connecticut River which alone can be regarded as undisputed all-rail territory.

The railroad-rate problem remains unsolved and it has again been demonstrated that in the absence of swollen demand off-shore or impaired railroad service the Pocahontas and New River districts are adequate sources of supply for the greater part of this northeastern area—in fact insistent upon the lion's share. Through non-union policy they enjoy enough lower cost than sections accessible all-rail that in anything short of a buoyant market they dominate the seaboard trade. With rail rates as they are the smokeless shippers curry practically the whole of New England and there are few steam-using communities that elude their fine-tooth comb. Oil and hydro-electric power have made such inroads that the Hampton Roads agencies are in position to flood this finicky market, although partly for the same reason the total requirements are far less than during the war.

For the year recently ended, reduced consumption was perhaps the leading feature. Cotton manufacturing was particularly hard hit, and in many industries the inclination in January to store coal against possible emergency soon gave way to an entire lack of buying interest. Reserves were ample, receipts of coal for the first six months were well up to the high marks of other

years, but from July to December industrial purchases of more than meagre tonnage were the exception.

The goods trade, shoes, metal working and paper were all under blight of varying proportions, and deliveries on bituminous-coal contracts were as a rule far behind the quotas engaged. A few keen buyers profited by the dalliance between factors who loaded their wharves to the danger point and those who warehoused their coal in demurrage-laden bottoms, for in the end the seller went under the knife. It was the inexorable law of supply and demand.

A year ago it was figured that imports of fuel oil during the preceeding twelve months at the Port of Boston had been the equivalent of 4,250,000 net tons of bituminous coal, or an increase over 1921 equal to 500,000 net tons. Because California oil has been rapidly supplanting Mexican output the customs data for 1923 are not so significant, but according to oil statisticians the enhanced displacement for the year now ended was easily another 500,000 net tons, or a possible total of 4,750,000.

It is conceded that where local oil reserves last year were large they are now relatively less, a circumstance that would make actual consumption of oil for 1923 swell the estimated gain. That oil has made havoc with the steam trade is beyond question, but in spite of the marvellous flow of this attractive fuel there are certain indications of abatement. Besides broad assertions that the use of oil as fuel is wasteful, that the current surplus will be held in check, that relative costs are certain in the long run to favor coal, we know of steam users who find themselves obliged to consider resuming the use of coal.

At today's prices the consumer who can feed his boilers one-third anthracite

screenings and two-thirds bituminous coal discovers that only the cost of his oil installation stands in the way of oil. California oil will cost more than oil from Mexico; there are delivery charges on oil that are on all fours with coal, and barring a protracted strike that would be general in the bituminous regions it may be that 1924 will witness more of a reaction toward coal than the trade now anticipates.

FOREIGN COAL IN EVIDENCE

British steam grades were in evidence early in the twelve-month period, but January and February receipts could not be sustained. Ocean freight rates continued on a low basis—\$1.25@ \$1.50, Cardiff to Atlantic ports—but the prostration of prices at Hampton Roads the second half-year effectually put an end to movement in this direction. In December, however, there were colliers chartered for French ports for Hampton Roads loading, certain of them having brought Welsh anthracite to Boston with generous proportions of slack to enrich the available supply of low-price bituminous!

The unforeseen breakdown in prices of non-union bituminous coal early in the year discouraged further purchases of engine fuel from abroad, and even at the low range of ocean freights the West Virginia product at \$1.75 per net ton and less was too sharp competition for our English cousins. And it was from West Virginia that the New England roads took the greater portion of their supply during the period under review.

A committee of the Massachusetts Legislature named in the spring to examine into the coal industry made a rather more restrained pronouncement than is usual in political composition. It urged a review of railroad rates on bituminous coal as well as on anthracite, argued for the more extended use of bituminous in dwellings, and, refreshing for coal men to read, it lambasted coke producers for their "selfish policy."

Quality coals from the central Pennsylvania districts were on a \$6 per net ton mine level in January, but as the weather caught up with the short sup-

ply of anthracite there was a gradual lowering of prices until in April they were around \$4. Beginning in June quotations on all grades drooped for the rest of the year, and in New England the product of Pennsylvania almost ceased to figure.

All-rail deliveries were reasonably well maintained to the time when Southern coals eased off, but thereafter the proportion of commercial bituminous coal entering the Hudson River gateways was relatively light when compared with the volume of railroad fuel rolling on early commitments. When No. 1 Navy Standard Pocahontas and New River sold at \$5.18 on cars Boston with slack at 50c. less, and favored with a \$1.32 rate to large mill centres the high tariff all-rail would leave but \$1.39 per gross ton f.o.b. mines in Pennsylvania. He who runs may sense the reason for the much restricted buying of even the highest grade Cambrias during 1923.

SEASON LACKED BALANCE

There was a period in May, when the smokeless interests sought to establish \$7 as a take-or-leave basis at Norfolk, that the South Fork producers had vistas for a few days of comprehensive business, but it was for a few days only. Most of them were so flustered by what seemed an inviting prospect that they declined tonnage they sorely needed later on. A large movement probably would not have been the outcome in any case, for the buyer has ways of reaping the advantage of hindsight, but it was considerable while it lasted and was a godsend to the rail roads serving Philadelphia.

Aside from that short spasm, dumpings at the Delaware River terminals after April were confined chiefly to high volatiles both for locomotive supply and for illuminating purposes, and even of these the volume steadily diminished until low totals were reached toward the end of the year. The bulk line was from Hampton Roads and it is with Pocahontas and New River that the record of 1923 is mainly concerned.

At no time during the year was there anything approaching the contract-making activity that used to be so characteristic of the spring months. The Navy purchases of 400,000 tons or so in April ranged \$6.50@\$6.72 per gross ton f.o.b. vessel at Norfolk, but in New England there were but few comprehensive orders placed at a fixed price. The Navy bids disclosed a firm

purpose to maintain higher levels than during 1922, but faced with uncertainties in their own lines, buyers here could not see their way clear to respond.

By late March, therefore, contract business was at rather loose ends, and few of the agencies could do better than continue the previous season's understandings and make prices on a mine basis only for April, leaving later figures to be determined as the market developed. The price range on these arrangements at the outset was \$3.50@\$4 per net ton at the tippie (\$6.44@\$7 per gross ton f.o.b. Norfolk), the price varying according to the class of the buyer, but by June the mine basis had to be modified materially. As in 1922, a large proportion of the Hampton Roads coals received here was through regular channels that had become customary since the war.

In January the smokeless coals were in short supply. Car service was erratic, prepared sizes were in strong demand in the West, and in New England there was an improving market for inland delivery. At the Virginia terminals prices ranged \$7.50@\$8.80 for standard grades, a level that was raised to \$9 by the end of that month, with \$11 a typical quotation on cars, Boston, and bituminous retailing at as high a figure as \$15 per net ton. But by February our buyers began making their exit. It was estimated that something approaching 25 per cent of the steam coal received early in the year was shipped in anticipation of household needs, and it was quite clear that production was far beyond normal industrial requirements.

CARRY COALS TO ENGLAND

Conditions underwent rapid change. Late in January the port facilities at Boston were congested; at Mystic Wharf 80,000 tons awaited discharge, and British coal was still being received. A month later saw mining less than 50 per cent normal in the smokeless districts and prices sliding off both all-rail and along the seaboard. There were traffic embargoes on the trunk lines, and while in March there de-

veloped a disposition to hedge on the course of the spring market, it was soon realized that there was little support for prices that were being sought.

It was in March that certain Italian and English orders materialized, and the trade was treated to another paradox. Situations had developed so fast that ships were passing on the high seas, some bound here with English coal on commitments of thirty days earlier, and others outward bound with American coal for Europe. A surplus of shipping both here and abroad depressed marine freights and for series of trips on short days for loading and discharging there were fixtures of coastwise steam tonnage at rates down to 55c., Hampton Roads to Boston, a level that had not been touched since 1914.

Transportation disabilities had been so persistent and were so recent it was but natural that there should be alarm in the spring over what were regarded as reserves entirely too small for New England's probable consumption, but by mid-June the market's extremely sluggish tone convinced the prophets that there was other ground for anxiety. The cotton mills were curtailing from a third to a half, about every hardening tendency was one after another eliminated, and the market settled down into old-fashioned summer dullness. From May 15 to Nov. 15, a full six months, the f.o.b. market declined steadily from \$7 to \$4.35 per gross ton at Hampton Roads, the on-cars price here suffered a similar drop from \$8 to \$5.18, and further declines were saved only by the most drastic and general cessation of mining. The retail price in Boston

SPOT PRICES F.O.B. MINES ON THE BOSTON MARKET OF MINE-RUN COAL FROM CAMBRIA AND SOMERSET COUNTIES, PENNSYLVANIA

PERCENTAGE OF FULL-TIME OPERATION OF COAL MINES AND TIME LOST BY CAUSES

Tug River District, W. Va.

sagged to \$8 at a time when anthracite was selling at \$16.

Until November every purchase was a poor one; and even at the low point it was extremely difficult to entice buying. "Market cargoes" flourished for a brief season, but the toll was too severe, and burned fingers shunned the fire. Toward the end of December it was said there was less coal on wheels at the Virginia piers than at any time in several years, and yet the average price had reacted only to a point barely above \$4.60 f.o.b. vessel. Consuming territory was saturated, and probably not for a considerable period will the market recover from the protracted inertia of the second half-year of 1923.

Thanksgiving time witnessed a slight indication of firmer prices, due partly to a further restricted output and partly to the final absorption of scattered lots of distress coal. Ostensibly the on-car figure at this end was hitched up to \$5.75, but at the time and later there was quiet selling at 50c. less as bargain-seeking buyers put in an appearance.

It was a disheartening season. Only rock-ribbed houses could stand the strain, and it would not be surprising if several of the smaller brokers follow

some of their colleagues into more stable trades where they are not so likely to be caught between the upper and the nether stone.

The year ended with stocks nearly as great as in 1918—probably greater when we consider their proportion to current consumption. The faint spurts of the last two months had worn off; there was virtual stagnation and none but a drab prospect for 1924.

NEW YEAR PROSPECTS

On the threshold of another season the forecast is complicated by a probable renewal of the wage controversy. Buyers who took on coal in December to meet all probable requirements as far ahead as May and June were per-

sued that in all likelihood prices would not be as low again for a long interval. Moreover, there is a reasonable prospect of suspension in the union fields and a determined effort to unionize operations that are not now organized. What will come of it is on the knees of the gods, unless it is in the mind of politicians to force a conclusion satisfactory to the union leaders. That would be in line with precedent in a presidential year!

SPOT PRICES F.O.B. MINES ON THE BOSTON MARKET OF MINE-RUN COAL FROM THE CLEARFIELD DISTRICT OF PENNSYLVANIA

Passing of 1923 on Atlantic Seaboard Unmourned by Soft-Coal Producers

Disaster Stalks in the Guise of Oil Competition and Sales at Prices
Below Production Cost — Anthracite Demand
Strong and Prices Hold Firm

By R. W. MORRIS

There will be little regret at the passing of 1923 by the soft-coal producers who ship to the Atlantic seaboard markets. The year was disastrous to them, notably through the loss of trade due to oil competition, principally in bunkers, and the selling of a considerable tonnage at prices, in many instances, below the cost of production. Quite the reverse is true of the hard-coal industry. Demand for domestic coals was strong during the entire twelve months and at no time were operators and selling agents compelled to force sales of the larger sizes. On the other hand the steam sizes felt the competition of oil and soft coal and nearly half a million tons of these coals have been lost within the last couple of years to the trade, the majority of this tonnage in New York alone.

Due to the scarcity of the domestic coals throughout the year many users of these sizes have been converted to the use of either oil, bituminous screened coals or coke, but the tonnage permanently lost is not believed to be large. Welsh anthracite to the amount of about 40,000 tons was brought across the seas to the New York, Philadelphia and Baltimore markets.

The year could hardly have been worse for the soft-coal operator. With the exception of the first few months of the year, prices were low and the producer had the choice early in the year of either selling his coal at a price or of closing his operation. Many chose the latter course. The result was that much of the coal offered to buyers in the New York, Philadelphia and Baltimore markets was of the better grades and much of it at prices usually asked for the poorer coals.

In the East the soft-coal trade played its part with other industries. Demand for coal, like production in industrial plants, was slow and uncertain. Contract coals moved steadily but in reduced volume, while spot buying was slow and considerable of the tonnage went into reserve stocks.

At no time during the year did the soft-coal market show any considerable strength. The year opened firm with prices around \$6 f.o.b. mine for the better grades. With a falling demand along the Atlantic seaboard, notwithstanding the lack of anthracite and the efforts of Federal Fuel Administrator Wadleigh to induce the use of soft coal in order to avoid a fuel famine, prices began to fall and, save for a brief period in late April and early May, continued to drop by degrees throughout the year. Even when it was apparent that there would be a strike in the anthracite region and during the period when the mines were idle, there was no activity in soft coal and most quotations either held steady or showed slight fluctuations.

While the old-line companies adhered to their price schedules, which, with the advance in September occasioned by the increase given the miners in the new wage agreement, did not go above \$9.25 f.o.b. mine, the quotations for independent domestic coals even in the time of least demand did not go below \$11 for stove and chestnut sizes, the preferred coals, and during the periods when demand was strongest reached \$13, with some sales reported at higher figures.

The introduction of other methods of heating big buildings resulted in less demand for buckwheat, rice and barley coals and caused considerable annoyance to the trade, with the result that retail dealers, who desired the domestic coals, frequently found it necessary to take some of the small sizes or bituminous coal with their orders. The effect of this was later felt in the tidewater market when these surplus coals were returned for resale at prices which in many instances were considerably below the current market quotations.

The soft-coal market started the year with lack of supplies and prices in keeping. Car supply was wretched and even the curtailed output due to the holiday season could not be taken care of. The better grades of coal moved either on contract or on consignment, and the coals offered for sale in the open market were of the cheaper grades. Quotations ranged from \$5 to \$6 for Pools 1, 9 and 10 coals but did not remain long on that basis. Railroads were buying and there was a demand for coke to help out in the emergency caused by the lack of domestic anthracite sizes. Reserve stocks in New York, Philadelphia and Baltimore were not heavy and with the scarcity of the better grades of soft coal many consumers were hard pushed.

The trend of the market along the seaboard is evident from the prices submitted to the U. S. Shipping Board at New York early in February for furnishing and delivering alongside vessels in that harbor monthly tonnages of either Pool 9 or Pool 71 coal. These

ranged from \$7.33 to \$9.10 per gross ton for three months delivery, and \$7.20 to \$8.74 per gross ton for six months delivery.

After the first six weeks of the year consumers began to look for bargains, buying only when they desired and prices were right. They held fair-sized stocks and the better grades were scarce in the spot-coal market. Operators became hungry for business and some thought was given to the closing of mines unless conditions improved.

Prices continued to decline. A contract was awarded for delivering 250,000 tons of Fairmont or Kanawha gas coals alongside, Boston and Providence, for railroad use at \$5.95 and \$6.04 respectively. In April quotations for Pool 1 coal reached \$4 and operators thought the bottom in prices had been reached, but before the close of the year this quality of coal was quoted as low as \$2.75 in the open market, with some sales reported at lower figures.

There was keen competition in the Baltimore market during the early autumn, due in part to heavy buying by one of the Canadian railroads as a result of a strike of Nova Scotia miners. Screened bituminous coals and coke were active previous to the settlement of the anthracite wage agreement, but following its signing they were almost discarded.

Demand for hard coal was heavy in all twelve months. Although, as indicated by the Geological Survey reports, production was maintained at a high rate throughout the year, receipts along the seaboard were not sufficient to meet the demands of consumers.

Demand for anthracite domestic sizes along the Atlantic seaboard was active the entire year. The strike of 1922 had left the country bare of hard coal and when Jan. 1 arrived there were no stocks available. The hard-coal consuming states were in the hands of fuel administrators and fair-price committees as well as distributing bodies whose efforts were devoted to seeing that the coal was evenly divided and that everybody was kept warm. Consumers in nearly all communities besieged retail yards while the dealers sought help from producers and selling agents.

In New York as well as other cities peddler pools operated under the direction of the State Fuel Administration bodies, and although the operators asserted that allotments were up to 60

per cent of former years, the loss of 40 per cent being attributed to the miners strike of the previous year, the public called for more coal. The use of substitutes was advocated by the authorities and largely adopted by consumers, many still continuing the use of coke and oil.

On April 1 anthracite mine operators reduced prices on steam coals 50c. a ton and two companies cut 15c. from their price for pea coal. No changes were made in the other domestic coal prices. Likewise cuts were recorded on retail prices in most of the Eastern cities. Immediate filing of orders was urged upon consumers by both retail

dealers and by the Federal Fuel Administration.

Soon after the resumption of mining on Sept. 20 the larger operating companies announced an increase in mine prices for the domestic sizes ranging from 70c. to 90c. for egg, stove and chestnut coals and 15c. to 30c. for pea coal. This was soon followed by increases of about 75c. a ton by retailers.

Early in December demand for independent coals fell off and quotations, which had held around \$12 for several weeks, became easier, dropping to around \$11 for stove and chestnut and less for the other sizes, with indications pointing to further cuts.

Bright Early Outlook Unfulfilled In Pittsburgh Market

After First Three Months the Coal Trade Waited in Vain for Relief from Depression—Anthracite Strike Scare Had Fleeting Influence—Connellsville Market Ran Similar Course

By B. E. V. LUTY

Except for the first three months, 1923 was a poor year for the coal trade in the Pittsburgh district. A combination of heavy demand and restriction of production by car shortage held prices at a high level during January and February, compared with normal times, but they declined sharply in March, being at an unsatisfactory level for the remaining nine months of the year. Pittsburgh district steam coal in the spot market was at \$3 or higher throughout January and at above \$2.50

throughout February, but by the end of March the market was down to about \$2.

For about six months after April 1 the trade lived more or less in hope that something would occur to lift the market out of its rut—a car shortage or some other influence—but nothing occurred except a mild rise in August, on the occasion of the anthracite suspension scare.

The Pittsburgh district sold heavily in the lake trade, getting a larger share of the business than in many preceding years, but at the expense of prices. Lake buyers practically made the market. Early in the season operators quoted on season contracts considerably more than the spot market, but lake buyers simply bought in the spot and prompt market until finally the operators yielded and sold for the remainder of the season at only a trifling premium above the spot level.

Production in the district was highest in August and September, reaching approximately 80 per cent of mine ratings.

Youghiogheny gas coal held much better in price than steam coal, the better grades being in control of strong operators, able to leave the coal in the ground rather than accept prices that would not net full depletion charges.

The district experienced strong competition from many adjacent fields. There was more competition from West Virginia than from the Connellsville region, where the best coal had a good outlet in beehive and byproduct coking, while the poorer coal, chiefly Sewickley vein, cannot compete at all in quality with the Pittsburgh seam.

Connellsville byproduct coal brought good prices during the first three months of the year. The spot market went down to about \$3 and consumers expected to buy second quarter on

AVERAGE SPOT PRICE, F.O.B. MINES, ON PHILADELPHIA MARKET OF MINE-RUN COAL FROM FAIRMONT DISTRICT

about that basis, while operators looked for a rise, and some were unwilling to sell beyond April at \$3.25. By the middle of the year competition had brought the market down nearly to \$2 and the average realization during the second half of the year was but little above that figure. In many cases the making of contracts was practically abandoned, the transaction of business occurring substantially by the buyer posting a price and accepting deliveries at the price until further notice.

The Connellsville coke market had gone well above \$10 during the strike of 1922 and was not only slow in declining but had its decline arrested in November of that year, showing a slightly higher price in December, and then a higher price still in January, 1923. Late in January the market began to soften, and this continued until the middle of February, when furnacemen seemed to become fearful that they would not be fully supplied during the second quarter. The pig-iron market was then rising rapidly. What amounted almost to a stampede occurred, and after one or two second-quarter contracts were made at \$6.75 the market advanced to \$7@7.25, while one or two contracts were made at \$7.50.

Almost immediately after the last second-quarter contract was made, and before the end of March, the spot market began to weaken, and then in the next two months it tumbled, so that by early in June coke could be bought readily at \$5, while furnaces were paying on their contracts an average above \$7.

Third-quarter contracts naturally proved much harder for the operator to put through than second-quarter contracts had been. There was a fair volume of business done at \$5.25@5.50, but some consumers refrained from contracting, preferring to buy from time to time, and they saved money, for during the entire third quarter the prompt market ranged well below \$5. For the fourth quarter there was little contracting.

Coke production in the Connellsville region increased quite sharply in the first three months of the year, held steady in the next three months and

then declined almost continuously and rather sharply in the second half of the year.

For the fourth quarter a Youngstown steel interest with byproduct ovens took a contract with a merchant furnace which normally had bought Connellsville coke, by naming a lower price than Connellsville operators could meet. The steel interest was faced with lighter blast-furnace operations and it was highly desirable to keep its byproduct ovens warm.

Monthly average of spot or prompt furnace coke and 72-hour selected foundry coke, per net ton f.o.b. ovens, Connellsville region, were as follows in 1923:

SPOT PRICES OF CONNELLSVILLE COKE, 1923					
	Furnace	Foundry		Furnace	Foundry
Jan.	\$8.30	\$9.25	July	\$4.60	\$5.60

June	5.00	5.85	Dec.	3.90	5.25

Year of Early Promise at Cincinnati Came to Blue Finish

Wide Diversity of Elements Tended to Muddle Market—Pressure Following Strike Lessens as Coal Pours In from All Points—Mild Weather Proves Finishing Touch

By HAROLD WILSON COATES

Greater variety to a year's endeavor in the coal business has scarce been witnessed at the Cincinnati gateway than in the one that has just closed. It did not run in streaks of fat and lean—it was either good or "good and rotten." Every element that there is to provide a scrambled condition can be found in turning back the pages to get a summary of the swing of the trade in the past twelve-month. Things that could be relied upon to chart the way went by the board and the close of 1923 found most of the trade at this point sitting around rather blue—with little roseate in the outlook.

And 1923 started out with the best of

prospects. The high tide of pressure for coal following the labor trouble continued with the dawn of the new year, and even though the union mines to the north, east and west were pouring out their offerings there seemed to be no let-up to the demand for West Virginia and Kentucky offerings.

Perhaps the earliest intimation that things were a bit out of the usual groove came in midwinter, when brokers and wholesalers as well as firms with direct mine connections found that lake buyers were not rushing madly into the market to make deals for the opening of navigation. By mid-February cars were being reported in distress and it appeared that the reservoirs were filling up with coal, a sure sign that the era of high prices was breaking and that if there were to be price readjustments these would be more violent than ever. The lake buyers held the whip hand, and they continued to hold it until the last cargoes were on their way. In fact holding to this one angle, lake purchases of coal failed to figure prominently in this market's affairs much after the latter part of August.

By April 1 nearly all of the buyers—except probably the takers of smokeless coal—were playing a waiting game. Salesmanship had to be reckoned with and the "order takers" of several months past were sent out to beat the highways and byways and turn in business. May saw a new element enter-

PERCENTAGE OF FULL-TIME OPERATION OF COAL MINES AND TIME LOST BY CAUSES

ing the situation. The weakened car supply, caused by the shopmen's strike of the year previous, was being remedied. More than that, new equipment was beginning to show on the roads, and this brought to an end, for the time, the question of whether the coal could be moved or not. In this respect it might be said that the statistics of the regional director for the American Railway Association will show figures for each week of the year ranging from 8,000 to over 10,000 cars a week being interchanged from south of the Ohio River to the north for 1923 and it is only three or four years ago that a 5,000-car or higher week was an exception.

The latter part of May and the first of June saw the flooding of the inland markets. Diversions from the lakes on several occasions threatened to "break" the market here, but prices kept the even tenor of their downward way (with the exception of the low volatile) and nothing seemed to stay the trend. For the first time in many months there came talk of lowering production and the July holidays saw some of the mines closed down with an intimation that they would be unable to resume until either volume business was obtained or better prices were offered.

August brought a peculiar situation. It was the old story—the coal came along without a definite destination and "spoiled the party." This grew so unwieldy that there were really two sets of prices for fuel passing through this mart. One represented a figure that miners of standard coals set upon their tonnage and below which they refused to budge; the other the day to day quotations from the brokers and wholesalers, sometimes \$1 to \$1.25 a ton below the set figures, but which had its ultimate effect upon the top prices. Domestic business was now getting the bulk of attention and with the screens going in again, slack had to be sacrificed as long as the price of sized stuff held up. September saw it ranging around 75c. a ton and the last of that month brought it even lower.

Now the autumn swing of business

should have been on—it was a weather proposition once more, but up to this writing old Boreas has failed to function. That has been the "last straw," for without Jack Frost the rail communications with the mines have been unimpeded and the interchange shows that production for the past three months has continued "top notch," even though reports come in from all quarters of mines closing down or suspending.

The first of the year saw the mad scramble for Pocahontas No. 3 coals still on. There was still the flavor of the "government price" in the air and quotations of \$7@\$.75 for the prepared sizes were being made by the standard companies. Most of their business was under contract or being allotted to customers, so that brokers could and did make sales at \$8@\$.85 for what tonnage they could lay hands on. Lump was quoted at \$6@\$.65 with about the same price for screenings.

From April 1 on, with the exception of a break in June, the low-volatile coals ranged pretty well around \$6 for prepared and \$4@\$.425 for mine-run and screenings. It is rather remarkable that these prices were maintained up to about the last of September while the high-volatile coals were struggling along facing week to week reductions. The first to feel the gaff was mine-run, which following the closing of active business of the lakes, dropped into the \$2@\$.3 range. Since then readjustments have followed that brought the price down to \$3@\$.35 for lump, \$1.75 @\$.225 for mine-run and \$1.25@\$.2 for screenings. At no time during the year did labor trouble disrupt the flow of this coal.

The southern West Virginia high-volatile fields still are the volume producers for this market. Those who keep an eye on Logan County assert that she will again create a record for coal shipped up the Guyan branch of the Chesapeake & Ohio. Until early autumn the Norfolk & Western high-volatile mines had their lean streaks, especially when motive power and car

supply were not of the best, but the summer business was all that could be asked. These latter mines responded quickest to the waning prices and some of them have been down for months rather than show "red figures" on the ledgers.

The story of the ups and downs of this territory as well as of the Kanawha and Coal River groups is told best in the figures when it is considered that last January 4-in. lump sold around \$5.75@\$.6; mine-run \$3.75@\$.425 for byproduct; mine-run steam at \$3.25@\$.35 and slack \$3@\$.35. By April the best lump was selling at \$4.25 top, mine-run at \$2.50 and slack \$1.75@\$.2. The midsummer spread saw virtually another dollar reduction and from that it has whittled off to the present low ebb.

The volume of tonnage that has been coming from the Hazard and Harlan fields to the Cincinnati market continues to show the upturn that has marked this as one of their primary markets for the past twelve years. The expansion of these fields as well as the extension of equipment there mean even more coal pouring through as time goes on. The word that the Louisville & Nashville and the Clinchfield roads will be "hooked up" so as to give a seaboard outlet through Southern ports is going to mean much. That figures in this review because of the virile prospects. During the past year there has rarely been a time when prices on Hazard and Harlan coals have been more than 25c. out of range with the same types of coal from the southern fields of West Virginia, so it would be merely a repetition of figures to go over that once more.

There is this exception, however: During the first three or four months of last year—and it always happens when prices perk up—there was a differentiation in the price of byproduct and malleable, the good gas coals and just coal (or steam, for lack of a better or more suitable name). Today all of these niceties both in buying and selling seem to have gone by the board. Strange, isn't it?

but \$1.50 at the lower Lake ports, 45c. lake freight, 25c. or less across the docks and \$2.25 rail freight to the market battle ground around the Twin Cities and below, was strangling the normal Illinois northward flow. Also cheap Pocahontas mine-run at \$1.50 or even less cut into both Illinois and Indiana from the east. The result of this market scramble was a reduction of prices to a point where a large volume of Midwest coal moved at a loss—sometimes a heavy loss.

As the new year 1924 dawned most Midwest producers looked forward to April 1 as a definite stopping point, though a few were inclined to say: "Well, there's no use trying to whip this union into taking a reduction in wages, so the next best thing is to sign up so as to be sure the market stays flat, thus preventing any of these fly-by-night operators from getting back into the business, and then take our chances." Somehow I have an idea that's just what will be done.

At the beginning of the year prices were reasonable, but poor car supply cut down volume. In Illinois and Indiana prices were rather firm. Good association lump from southern Illinois brought \$5.50, though price-cutting independents at times sold down to \$4. Good southern Illinois screenings were \$2.75@\$. Fourth Vein Indiana lump and screenings moved at nearly those same levels. Illinois Standard district operators were able to make money with lump at \$4@\$.4.25 and screenings \$1.75@\$.2.

Viewed only from the standpoint of prices, the coal industry in the Midwest was "sitting pretty," but poor railroad service cut the volume low. Whereas Illinois and Indiana started the year at about 65 per cent of capacity, they both went into February at about 50 per cent and Kentucky slumped even more. There was no great interest in storage among any class of consumers

except gas plants. Nobody was crying for coal and it can frankly be said that car shortage is all that saved the market from a bad February slump.

The general shading of the market started late in February, when Indiana and Illinois clipped from 25c. to 50c. from everything except big lump. By that time a good deal of smokeless from West Virginia had begun to percolate into the Midwest at prices that were tapering down. Pocahontas lump and egg that had sold in Chicago at the beginning of the year for \$8 was easy to get at \$7.25. By March 1 it stood at \$6.50 on its steady downward way to the \$3 it reached by the end of the year. Pocahontas mine-run, which opened the year at \$5, coasted down all spring and summer until it reached \$1.40@\$.1.50 awhile before the end of the Lake season. Periodically all year the Midwest caught floods of this coal.

The spring struggle to get consumers to contract was vigorous but largely unavailing until the government officially advised industrial summer storage on a large scale. Then the Western railroads that were in soundest financial conditions began putting coal on the ground. The Illinois Central, Burlington and Big Four entered upon great programs ranging up to a million tons, accepting, at various times, about every size of coal produced on their lines. These contracts varied from \$2.50 to \$3. They made nobody rich but they resulted in long runs of production.

The car supply, which had been so poor during the winter months, improved rapidly with the coming of spring. That started the general tumble of prices. By late March the percentage of causes for lost working time at mines experienced a complete change. That charged to bad car supply flopped to "no market," and "no market" increased all summer long, getting low enough at times so that the average for the year was close to 50 per cent.

In the domestic trade various price experiments were tried by Midwest producers. May 1 the Franklin County

lump price was hoisted from \$3.85 to \$4.10 and on June 1 to \$4.35, where it remained, so far as circulars were concerned, until late in the autumn, however. The circular price was by no means maintained, and finally, with the virtual collapse of the market early in December, Franklin County lump caved to \$3.75 and other Midwest coals followed. Central Illinois was \$2.75; Fourth Vein Indiana, \$3.25; Mt. Olive (Ill.), \$3; Standard district, \$2.75, and West Kentucky, \$2.75.

All during the summer the market was so lifeless that price cutting created no business. For a long time in St. Louis practically no trading was done, except a little on the lowest priced coal within reach—Standard district, whose lump at one time got down to \$2. In those months the best lump nearby—Mt. Olive—moved practically not at all because the operators were unwilling to give it away for less than \$3.

All the while the Midwest drive into the Northwest by rail was going on. Coal moved into that territory at times but on narrowest margins and against throat-cutting competition.

The anthracite strike in September had very little effect on the flat Midwest domestic market. Not much home-produced coal was sold because of the fact of the strike, though soft coal was favored by the increase which Governor Pinchot's strike settlement slapped onto the price of anthracite. This increase added 50c. to 90c. a ton in Midwest retail yards. But by the same sign a large number of householders shifted clear away from all coal and

PERCENTAGE OF FULL-TIME OPERATION OF COAL MINES AND TIME LOST BY CAUSES

installed oil burners. The tonnage of smokeless used in the Central West also increased greatly, so that Midwest coals lost more than all they might have gained by reason of anthracite's difficulties.

The steam market naturally suffered all the year. Screenings began to pile up around Midwest mines. Big mine-run contracts to railroads gave some relief at times during the spring and summer, but the open market always was full of steam coal. Prices slid lower and lower. Very few producers put any screenings on the ground. When Franklin County screenings bumped down to \$1.75 in June, central Illinois, Standard district and west Kentucky fines were at \$1.50 and sinking. Nothing stayed the grand slide.

In such periods medium-grade fields got screenings business because they had short freight rates to strong markets. This is what enabled central Illinois and Indiana to sell screenings in Chicago for \$1.50 when other regions could hardly dispose of any at all. But the worst was yet to come.

In October producers tried their best to hold back their screenings so as not to give them away. The railroads stood for tied-up cars as long as they could and then forced the disposal of great volumes of this coal on wheels. The result was Franklin County sank so low that it touched \$1 now and then, central Illinois got down to 80c. and Standard district to the ridiculous level of 40c.

In November, with such conditions prevailing in the steam market, the Standard Oil Co. quit trying to operate its two mines in Illinois, shut them down cold and contracted for about all the available central Illinois screenings output to April 1 at \$1.25.

General shutdowns all over Illinois and Indiana finally prevented the steam market from going clear through the bottom, and by the end of the year production was down low enough so that Franklin County had pushed its screenings back up to \$1.65, central Illinois to \$1.50, Standard district to \$1.10 and west Kentucky to 85c. @ \$1.

Kentucky had a troublous year. While the market during the early part

of the year ranged from \$2 to \$3 above the same months of 1922, car supply choked all Kentucky down to about one-third of its potential production until well along into the spring in time for the Lake season. By that time, however, prices had dropped until good eastern Kentucky lump and mine-run, which had opened the year at \$6.50 and \$4, had declined to \$4.25 and \$2.85. By the middle of the summer this same coal had slumped another dollar.

During October, with the bottom about out of the market, in spite of fairly good fag-end Lake movement, some ridiculously low prices were quoted on various Kentucky coals. Elkhorn mine-run in distress and in the hands of jobbers sold down to 85c. Harlan and Hazard gas mine-run was circulated at the time for \$2@2.25, but some of it sold as low as \$1.50. Toward the end of the year \$3.50 was a good price for best eastern Kentucky lump as compared with \$6.50 the December before, and nothing interfered with the production of it except the trifling fact that hardly anybody wanted it at any price.

Two factors added to the Kentucky perturbation during the summer. One was the unwonted activity of strip pits both east and west, which had a demoralizing influence on the market at times because of their production of nearly 3,000,000 tons, or about twice as much as in previous years. The other factor was the wage cutting of a scattered string of operators up and down the non-union eastern end of the state. The operators' associations strove to

hold these interests in line, but with only moderate effect. The wages of 1917 were paid in several mines during November and December, with the inevitable market undercutting. Somewhat of chaos was created in that section including an unexpected show of secret union strength and the usual movement for consolidating many mines under a few ownerships was brought to the fore.

Western Kentucky, also handicapped during the spring by car shortage, produced a vast tonnage during the summer and, with the aid of low prices, sold it all over the middle of the United States, striving for new markets. This coal was a serious factor as far north as Minnesota. Where a nation is full of coal, however, and where margins of profit are narrow or absent, such production could not continue; so by the end of the summer about 75 Kentucky mines were shut down. Many of them reopened in September only to shut down again in November after a hopeless effort. The general hope—and expectation—in all Kentucky is that the union bituminous coal fields of the nation will be tied up by a long strike beginning April 1.

SPOT PRICES, F.O.B. MINES, ON THE LOUISVILLE MARKET OF COAL FROM WESTERN KENTUCKY

West's Production Broke No Records and Market Is Lifeless Generally

Efforts to Get More Favorable Freight Rates Were Unavailing
But May Produce 1924 Results—Labor Troubles Few—
Two Terrible Explosions Occur

Little delight was registered by the coal producers of the West and the Southwest during the year 1923. In the mountain states Utah dropped about 600,000 tons under last year's production and Colorado rose about 500,000 tons above it, but this does not mean that the two states experienced a lively market at any time, and the price of their coal was low. In Kansas and Oklahoma the wails of the coal man are loud and mournful. "The least profitable season in history," they say, and the fact that Kansas production went 600,000 tons above the 2,955,000 tons of 1922 helps not at all. Average Kansas selling price was \$1 a ton less than in 1922. In the other Southwestern states—Oklahoma, Missouri and Arkansas—the output fell well below that of last year.

The hope of changes in freight rates out of both these two groups of Western fields during the year was not realized. The mountain producers met the dock coal at the usual points in the North and Northwest and could not drive further. The strong appeal for more favorable rates from the mountains into the Missouri River region was not granted during the year but Colorado men are hopeful of aid from this source soon. If it comes, markets will be extended. The Southwesterners tried in vain to get an important readjustment of rates on coal from their own and the Illinois fields into the Kansas City-to-Omaha territory, and so there was no general change in competitive conditions except that Illinois producers, hampered by stiff competition elsewhere, shipped more coal into Kansas and Nebraska than usual.

Thus the year ran its course with nothing much in its favor except a comparatively calm performance by labor. Uncomfortably short running time in all fields a good deal of the year offers no good argument for an increase in union wage scales for 1924 but producers in the union fields of the Central West look for a cessation of labor for a while after April 1 in which

to get the present labor contract renewed. In Wyoming and Washington union operators want no cessation. Many of them are ready to sign a continuance of the contract right now.

In Kansas and Oklahoma oil competition was as sharp as ever, but the operators snatch at the straw of hope that oil prices may rise during 1924. To regain the market lost to oil it is necessary to lower the cost of production and increase dependability of supply. Since labor is the determining factor in both, operators look forward with exceeding interest to see what attitude union labor takes in the coming negotiations.

Two fearful explosions marked the year as particularly costly in life. On Feb. 8 a blast in the No. 1 mine of the Phelps Dodge Corporation at Dawson, N. M., killed 122. The other explosion killed 99 men in the Frontier No. 1 mine of the Kemmerer Coal Co. at Kemmerer, Wyo. Seldom has the West suffered so heavily.

The opening of the year was not particularly encouraging anywhere in the West or Southwest. Car supply in Utah and Wyoming ran only about 70 per cent but that was ample to enable the mines to produce all they could readily sell. Colorado trailed along about 15 per cent to the rear. In Kansas, with car supply at 40 per cent, lump sold for \$5.50, mine run, \$3.75, and screenings, \$2.50. These were circular prices, which the trade strove to maintain for a long time thereafter. Arkansas, with about 25 per cent of the rated allotment of cars, was not kicking for more, because, as usual, that state was having a hard time to

move what it produced at \$6@8 for lump, \$3.50@4.50 for mine-run, and \$2 for screenings.

As the winter advanced into spring the Far West continued to produce fairly well with running time better than 75 per cent. Utah and Colorado both dropped to little above 50 per cent, but regained a little with a rather raw March. Kansas and Oklahoma slid far below that. While the East, especially West Virginia and eastern Kentucky, was suffering keenly for want of cars, the West had all the cars it could use and plenty more. "No market," and nothing less, was the affliction. In Kansas City in early March the market was as full of holes as a Swiss cheese. Circulars were not changed, but undercutting was going on generally and became worse.

Late in March Kansas dropped lump from \$5.50 to \$4.50 in an effort to get business. The expedient helped only a little. Colorado shaded domestic a dollar to encourage spring buying, but with only modest results. A new low rate on the C. M. & St. P. and the Northwestern gave mountain states coal some encouragement in the Dakotas. Then came a little spell of cold weather all through the trans-Mississippi region and "no bills" in both Kansas and Colorado fields were hurriedly cleaned up before the weather again warmed and the summer began to stifle the trade.

In April shutdowns in Kansas became so numerous that Governor Jonathan Davis began his now famous official inquiry, at the instigation of union miners disgruntled by loss of working time, to determine whether the laws of supply and demand could be tinkered up so that the miners might work. He found they could not. The operators' main effort, failing to find a ready market, was to get a change of rates into the Missouri Valley region, either to give the Southwest a reduction or competing Illinois an increase. No adjustment has yet been made.

In the Rocky Mountains some raw weather in May helped the market and the usual periodic landslides choked off Routt County by stopping up a tunnel or two on the Moffatt road. Wyoming worked an average of approximately 55 per cent that month, Colorado 45 per cent and Utah a little less. Summer storage prices still were helpless to awaken the market. A slight decrease in intrastate freight rates on coal announced that month had the ef-

fect of pulling prices down another 25c. or so, again without much market effect.

Utah's market picked up during June, thanks to real industrial activity in that state on the part of smelters and copper companies and the beet-sugar making campaign. Running time for the state climbed to about 60 per cent. Even domestic trade there picked up a little, but there was little lifting of prices. Steam coal moved on contracts at \$1.25@\$.150. By July 1 Colorado prices had firmed up noticeably and the upward trend toward autumn business started. Good lump advanced 25c. as a starter, but this warning that summer storage prices were going off did not put much life into trading.

One of the noteworthy contributions to the summer's coal history was the campaign of public education which the Southwestern operators put on in their principal markets, such as Kansas City. In a long series of well-done advertisements, the producers laid the cards on the table so that the people might see something of what coal cost, why they should not wait until the dead of winter to buy and why they should give up belief in "coal baronism." It was a first-rate effort. Of course it did not cause an immediate and noteworthy strengthening of the market but some of those back of it felt that it established better feeling between the coal man and the public.

Another effort of importance—futile but interesting—was the attempt of the Kansas operators to get the union to agree upon a scale for mining machines. After much jockeying and many meetings of a joint subcommittee the two parties failed of agreement. The operators offered first a differential of 15c. below the hand scale of \$1.25. The miners would agree to nothing over 6c. The operators finally offered a compromise of 11c. This was refused, and the effort was abandoned. Today there is no machine scale in Kansas though there are machines at several mines where union domination is not complete.

On Aug. 1 prices in the mountain states began noticeably to stiffen, and a slight market pick-up appeared. Most domestics advanced 25c. Utah noticed a pick-up in Pacific Coast and Northwestern trade and domestic buying in Utah was fairly well started, but not in sufficient volume to exhaust the considerable stocks that retailers put in earlier in the summer. By the end of

August the whole West felt an improvement. Kansas and Colorado were getting three full days' running time each week and Utah was doing almost as well. This betterment continued through the middle of September, but turned again about Oct. 1, so that the production curve dipped once more and running time in all fields fell down below 50 per cent for awhile.

Late in October the curve rose noticeably so that both Kansas and Colorado worked more than 60 per cent

of the time and even Utah increased its output some. Then came the drop in December, when all fields, especially Utah, declined. Working time there was barely 50 per cent. Low production of domestic sizes all through the mountains at least had the virtue of stiffening up screenings. In Kansas and Oklahoma, with very low running time, coal of various sizes was piling up at the end of the year and Arkansas was about shut down. Thus ended an unprofitable year.

Northern West Virginia Set New Record For Production in 1923

Output, 27,024,050 Tons, Exceeds That of 1920 by 4,000,000 Tons—Financial Conditions Not So Rosy—Operators Discouraged—Yield of Sewickley Coal Growing

By H. A. WILLIAMSON

To Dec. 15, 1923, northern West Virginia, comprising about twelve and one-half counties, had shipped 27,024,050 tons of bituminous coal, the largest annual output in the history of the region, being over four million tons more than was produced in 1920. This large output, however, is not reflected by equally bright financial conditions. The price of coal steadily declined since the beginning of the year and by Dec. 15 the average price per ton probably was well below \$2—possibly around \$1.75—although accurate figures on this are not yet available if they ever will be.

This is the first year for a number of years that the operators appear actually discouraged. The smaller companies, with little or no overhead, are able to close down their operations and thus save themselves to a certain extent, but companies of any size are obliged to continue operations even though the coal is sold at ruinous prices. As the situation appears now the extremely small and very large companies with their long experience, are going to be able to weather the situation in good shape, but the companies between the two extremes are having a hard financial struggle, and many of them, if they do not actually fail, will have losses from which they probably never will recover. The northern West Virginia operator knows to

his sorrow that if the consumer is not getting cheap coal in 1923 it is certainly not the operator's fault.

One of the outstanding features of 1923 was the production of Sewickley coal in the Scott's Run district of Monongalia County. Practically the first Sewickley coal was mined from this district in 1916, when 19,041 was produced; in 1921 about one million tons was produced and to Dec. 15 in 1923 the total coal loaded from the Scott's Run district was 3,429,150 tons, of which it is estimated that approximately 2,750,000 tons was Sewickley.

The Lake trade, generally conceded to be lost to northern West Virginia because of the differential between freight rates for Ohio and northern West Virginia, has been revived strongly this year but probably at the sacrifice of any possible profit and only because the shippers were willing to accept almost any price. The region shipped to the Lakes up to Dec. 15

Logan District, W. Va.

PERCENTAGE OF FULL-TIME OPERATION OF COAL MINES AND TIME LOST BY CAUSES

2,273,900 tons. If prices return to anything like "reasonable profit," however, there will be practically no Lake trade from this region. The freight differential again was increased by 10c. per ton in 1923. At the beginning of 1917 the differential was 25c. per ton and during that year it was increased to 40c.; now it is 50c. Normally nearly a third of our production should go to the Lake trade and probably would even at 25c. differential, but with 50c. it is impossible and this must be remedied or shipment of this percentage of the region's production must cease with much resultant idleness.

The first months of the year were marked by considerable nervousness on the part of both miners and operators as to the possibility of strikes during the year. All parties concerned were pretty well fed up on labor troubles but there was worry as to what outside influence might do. Nothing serious developed, however, and the old confidence that existed between miners and operators before the union entered the field may be re-established more strongly than ever if sinister outside influences can be held in check.

Naturally with so depressing a year new development has been at a standstill, yet trade in coal lands has been constantly going on and several rather large deals have been put through. While naturally it cannot be confirmed rumor has it that at least a major portion of the dealing is in the interest of one or two railroad organizations intent on securing reserves of coal for future development.

All the usual evils have been in evidence during the year—fear of strikes, assigned cars, car distribution, increase in freight differentials, investigating committees, Coal Commission, representatives of the Department of Justice, federal taxes, state sales taxes and so on. The miner is worried because, except for a few fortunate mines having contracts, work is very slack; the operator is worried because of all the things enumerated above and a lot of others, 1924 is coming in with the region in a gloomy and downcast condition.

Restricted Demand for Commercial Coal Marked Year in Alabama Market

Consumers Without Contracts Kept but Little Ahead of Actual Requirements—Making of Furnace Coke Absorbs Increased Tonnage—Union Influence Fades Out

By H. B. McLaurine

The Birmingham market was featured by a very restricted demand for commercial coal throughout the year. Apparently assured that the mines would produce an adequate and uninterrupted supply of fuel, non-contract consumers adopted and maintained a policy of providing for their needs only a short while in advance of actual consumption, and no interest was manifested in the accumulation of stocks, necessitating uninterrupted efforts on the part of brokers and sales organizations to dispose of the output in excess of contract obligations assumed by the mines. However, there was a disposition on the part of operators to mine little coal in excess of the quantity they had previously been able to dispose of and the problem of distress fuel was at no time serious.

The usual contracts were renewed by the railroads and other utilities and industrial plants accustomed to using this means for insuring a steady and dependable supply of fuel, as such agreements expired. Quite a heavy

tonnage over and above the previous year was absorbed in the manufacture of furnace coke, as an unusually active iron market kept in operation beyond the first half of the year an abnormal number of stacks. The demand for foundry coke went hand in hand with the active iron market and the commercial output was heavy for a like period. Quotations ranging from \$8 to \$9 per ton declined to \$6.50 to \$7 f.o.b. ovens when the dull period was reached.

The development of bunker business through the Southern ports made no material progress during the year. The trade in this direction was hard hit by the cheap crude-oil prices which

SPOT PRICES F.O.B. MINES OF THE BIRMINGHAM MARKET OF COAL FROM ALABAMA FIELDS

prevailed at Gulf ports, many thousands of tons of bunker fuel being displaced by the substitution of oil-burning equipment in vessels with home bases at New Orleans, Mobile and Pensacola, as well as numerous craft which called at these points formerly for fuel-coal supply. Only a limited amount of coal was exported.

Hydro-electricity made further serious inroads into the domain of fuel coal at many interior points, municipal electric plants with steam-driven equipment being taken over by the Alabama Power Co., as well as numerous industrial plants being equipped with hydro-electric power. Several large pipe plants in the Birmingham district installed equipment for burning by-product gas instead of coal. These several factors vitally affected the marketing of Alabama coal.

The domestic demand was good with the exception of the last quarter, when unseasonable weather and consequent inability of retailers to dispose of their stock accumulations brought about a dull condition in the trade. During the first nine months of the year domestic coal moved in a most satisfactory manner. Contracts were more extensively entered into during April, the beginning of the coal year, than had been the case for several seasons past, and together with the spot demand which prevailed during this period afforded ready disposition for mine output.

Quotations on steam coal showed only slight decreases at the close of the year over the schedules in effect in

January. Domestic grades took on a gradual increase from the base prices effective April 1, as was customary, the quotations in effect in December being slightly higher in some instances and lower on other grades than ruling prices when the calendar year began.

It is estimated from figures now available that production for 1923 will approximate 19,000,000 net tons, or from one-half to three-quarters million tons in excess of the previous year. This increase probably should all be credited to furnace company mines, little of which found its way into commercial channels.

Several million dollars was involved in the organization of new mining enterprises and increases in capital stocks of going concerns for improvements and modernization of plants and equipment. Mergers involving a capitalization of perhaps eight to ten million were consummated, the DeBardeleben Coal Corporation taking over the properties of the Empire Coal Co., DeBardeleben Coal Co. and Corona Coal Co., and the Pratt Coal Corporation acquiring the holdings of the Kershaw Mining Co., Dora Fuel Co. and extensively developed and virgin coal lands of the Bryan Coal Corporation in Walker and Jefferson counties.

Operations at Alabama mines were not seriously hindered by car shortage, although some loss of time was occasioned in the first quarter on account of lack of equipment, due to some extent to faulty distribution.

Labor conditions in the main were entirely satisfactory, amicable relations being maintained between operators and employees. The only disturbance

of any consequence was the strike of union miners at the Beltona Mine of the American Mining Co., when officials declined to renew an expiring contract with the union. The places of these men were quickly filled and little tonnage was lost. The year marked the passing of the influence of the United Mine Workers in Alabama, the autonomy of District 20 being abrogated by the national organization after a struggle since about 1893 to establish permanent and effective domination of mining labor in this district, the open-shop being thoroughly and irrevocably established as the policy of Alabama operators.

British Trade Unsettled at Year's End

Unusual Activity Throughout First Half of Year—Decline Began in June—Production and Shipments Still Fairly High—Lighter Demand Causes Rapid Fall in Prices

BY C. H. S. TUPHOLME

Though the coal industry throughout Great Britain may be said to have improved gradually during the past two months, it is actually in a very unsettled state. The year 1923 opened full of promise for both the Welsh and the north of England coal fields; the demand from Europe, especially Germany, and also from America was considerable, and for some time such rapid recovery was made that even pre-war exports were exceeded. This unusual activity lasted nearly half the year, but since June a gradual decline has set in, and though both production and shipments are still at a fairly high level, a shortened demand has caused a rapid fall in prices.

An instance of this fall may be taken from the Welsh steam coal market. In June the operators were able to obtain any figure up to 42s. 6d. per ton for best Admiralty large steam coals. As a result the industry was making good profits, and the miners' wages were raised from the minimum of 28 per cent above the 1915 standard, where they had been almost stationary for nearly a year and a half, to 41.47 over the standard. At the present time Admiralty large steam does not command above 27s. 6d. per ton in the open market. This decline has meant that while some pits are still able to show a narrow margin of profit, the majority are operating at a loss.

The output over the second half of the year, with the exception of one week, has been consistently over the 5,000,000-ton mark. South Wales alone is still producing over 1,000,000 tons per week and is exporting 600,000 tons, so it cannot be said that there is any fault either with the volume of output or of trade. In spite of this the operators are confronted by a serious problem. Production, especially at the newer and more modern shafts, is very high. Thus, as it is essential to obtain heavy outputs so as to obtain economic operating costs, there is a continual striving after higher and higher output, and this rivalry between pits grows keener every day.

Buyers abroad appreciate this position and quite naturally take full advantage of it. Thus European customers especially have suspended their custom of placing contracts for de-

livery over long periods, now basing their orders on the fact that the colliery operators must accept current business at low figures so as to keep the pits going and so endeavor to avoid the additional costs incident to a stoppage.

This probably is the chief factor in the present unsettled position and accounts for the drop in the price of Admiralty large steam on the Welsh market from 42s. 6d. to 27s. 6d. in the space of a few months. Naturally there is considerable difference in the various classes of coals marketed in South Wales, and while only the figures for Admiralty large steam have been quoted, identically the same argument applies to all other kinds.

The coal industry was decontrolled in March, 1921, and from that time to the late summer of 1922 the operators had to bear exceptionally heavy costs, arising not only from a three months' strike but also on account of the rapid decline in selling prices which followed.

Fortunately for many pits, which would otherwise have had to close down, a demand for coal arose in the United States because of the strike there, and also on the Continent on account of the suspension of operations in the Ruhr. These two factors so changed the outlook of the entire British coal trade that the few months' comparative prosperity enabled the pits to recover. Unfortunately, this prosperity was too short-lived to enable the collieries to collect any substantial reserves. There is no doubt that the next three months is to be a crucial period for the entire trade.

This year has seen the culminating point of a rather remarkable recovery from the disaster of the national strike. Nineteen hundred thirteen was a record year for the industry; the output in that year in South Wales was 56,830,000 tons. In 1920 the output was 46,250,000 tons; in 1921 (the year of the national strike) it was only 30,570,000; 1922 saw production rise to 50,325,000 tons. This year, up to the end of the September quarter, the output of the South Wales pits amounted to 41,000,000 tons, which is at the rate of 55,000,000 for the year, or nearly up to the pre-war record. The total output of the British pits this year up to and including the week ending Dec. 1 is 247,577,000 tons, which is at the rate of over 260,000,000 for the whole year—quite a creditable performance.

This total it must be remembered is being produced in a seven-hour day against eight hours before the war, and by men fluctuating in number between 1,160,000 and 1,180,000. In the Welsh coal fields alone 243,000 men are employed against 233,000 before the war. The wages of these men are stabilized by the Agreement of 1915 at a minimum of 60 per cent above the pre-war level. It follows, therefore, that the Welsh operators must get at least 60 per cent above pre-war prices; otherwise their industry is in danger.

Realizing that new pits must be sunk to replace those worked out, many of the leading concerns during the prosperous period at the beginning of this year began operations on new shafts in unworked areas. These pits must be worked for some time before they can be regarded as paying propositions, and the burden of the operators is thereby increased. Costs have gone up on these new pits and suitable labor has not been easy to find.

Many of the new shafts have been sunk in virgin districts far removed from the centers of labor supply. In

During the first ten months of 1923 the production of coke was 1,613,000 tons as against 808,000 tons for the corresponding period of 1922, an increase of 805,000 tons. In 1913 the French

When with the beginning of the occupation of the Ruhr Germany ceased

PERCENTAGE OF FULL-TIME OPERATION OF COAL MINES AND TIME LOST BY CAUSES

mines were producing around 2,635,000 tons of coke, including 2,445,000 tons for the Nord and Pas-de-Calais, a monthly average respectively of 220,000 and 204,000 tons. Production in the northern coal fields during the first ten months of 1923, was about 1,045,000 tons and the output is increasing every day, especially in the Nord Department. The independent cokeries have produced an average of 117,000 tons a month.

Production of patent fuel for the first ten months of 1923 was 2,536,200 tons of briquets and ovoids against 2,271,000 tons in the corresponding months of 1922, an increase of 265,000 tons. In 1923 the Nord and Pas-de-Calais mines produced in ten months about 1,290,000 tons and in 1913 1,802,000 tons, or 150,000 tons a month.

France imported 21,620,509 tons of coal during the first ten months of 1923, as compared with 18,192,441 tons for the corresponding period of 1922. The 1913 imports for the whole year were 18,693,000 tons, or a monthly average of about 1,558,000 tons.

Imports of coke for the first ten months of the year were 2,839,549 tons against 4,162,280 tons in 1922. Comparison of these figures shows the deficiency of supply, for which Germany is responsible; in fact, reparation deliveries up to Oct. 31 were only 1,476,427 tons, against 3,522,442 tons for the past year. Total imports in 1913 were 3,071,000 tons, or 256,000 tons of coke per month.

During the first ten months of 1923 Great Britain supplied France with 14,904,010 tons of coal and 358,983 tons of coke; shipments from the United States totaled 620,128 tons of coal and 168,856 tons of coke.

French occupation of the Ruhr began Jan. 11. Soon thereafter the Germans voluntarily cut down reparation deliveries; from Jan. 20 on France received only insignificant tonnages. France immediately bought coal in Great Britain and contracts were placed with American firms. British shipments of coke were important during the months of February, March and April. American coke was received mainly in May (76,696 tons), June (33,103 tons), and July (44,044 tons). Since July imports of British and American cokes have been very small.

Imports of patent fuel for the first ten months of 1923 were 624,541 tons, as compared with 1,048,711 tons during the corresponding period of 1922. In 1913 1,086,000 tons was imported, or a monthly average of 90,000 tons.

France was actuated to exporting coal through her proximity to Belgium, some of her collieries being nearer to part of the Belgian consumption centers than some of their own mines. France also exports coal to Switzerland and Italy, two countries very poor in coal supplies.

During the first ten months of 1923 coal exports amounted to 1,840,474 tons, including 941,192 tons to Belgium (Belgian exports to France in the same period were 1,895,338 tons); 326,279

tons to Switzerland; 93,268 tons to Italy; 213,721 tons to the Saar during the strike and 55,008 tons to Germany. Exports for the corresponding period in 1922 were 1,551,726 tons, or 200,000 tons below the 1923 level. The average of exports for 1913 was 109,000 tons a month.

Coke exports from January to October, 1923, were 385,671 tons, including 221,356 tons to Italy, 114,567 tons to Switzerland. Exports during the first ten months of 1922 were at about the same level, the monthly average in 1913 being 19,250 tons.

Exports of patent fuel were about 200,000 tons for the first ten months of the year just past. Switzerland was supplied with 130,000 tons. During the corresponding period in 1922 patent-fuel exports amounted to 80,000 tons. In 1913 the monthly exported tonnage was 16,000 tons.

Apparent consumption of coal in France—that is, production plus imports less exports—was lowest in February, when it amounted to 3,062,360 tons, and was highest in June, when it was 5,657,634 tons. The consumption by months, in tons, was:

January.....	4,746,376	June.....	5,657,634
February.....	3,062,360	July.....	5,510,471
March.....	4,732,829	August.....	5,458,460
April.....	4,829,505	September..	5,660,812
May.....	5,090,535	October.....	5,502,760

The prices generally applied on Oct. 1, 1922, were maintained in January, 1923. At that time prices changed according to the region to which coal was to be delivered. In the inland zone surrounding the coal field, prices were higher. In the Paris area, where British and Belgian producers compete, but with rather heavy transportation charges, prices were lower than in the local zone; in the so-called "British, Saar and Belgian zones"—that is in the region where imported coals are better situated as far as transportation is concerned than the Nord and Pas-de-Calais products—the latter must evidently get the benefit of lower pithead prices; and in the district outside of the British, Saar and Belgian zones, where

the products of other French and foreign coal fields can be found, prices were 1 fr. higher.

The Nord and Pas-de-Calais companies on Feb. 17, 1923, granted their employees wage increases of 3.25 fr. a day for adults, to be divided as follows: 2 fr. dating from Feb. 1 and 1.25 fr. dating from April 1. While the index of living remained unchanged, the salaries, thanks to these various increases, corresponded as of Feb. 1 to the index of the last three months of 1921.

As soon as this decision was taken, selling prices were revised. Beginning April 1 prices of sized products were raised from 13 to 26 fr. per ton, up to Sept. 30. Briquets and ovoids also were raised 5 to 10 fr. a ton, but industrial coal and metallurgical coke prices were unchanged. On Oct. 1 these prices were maintained and quotations would still be on the same level had not the companies been obligated to grant further wage increases at the beginning of November, varying from 1 to 3 fr. and as much as 5 fr., which caused an increase of 5 fr. in industrial coals, 10 fr. on sized products except beans, which was raised only 5 fr.; 5 fr. on ovoids and 10 fr. on large coke.

New rates also have been applied in the other coal basin, following the example of the northern collieries, and on a similar basis.

Summing up, as the reparations problem has not yet been solved, we cannot expect 1924 to be an era of industrial prosperity, though there is not much probability of a shortage of fuel. Nevertheless unless the Ruhr agreements fully give what France has a right to expect, the present year will not be a period of abundant coal. The main point lies in the amelioration of the coke situation, but from the present outlook, it is extremely unlikely that there will be a repetition of the precarious condition that prevailed during the past year.

Prices, except for coke, are generally expected to be higher in 1924.

Spot Prices, F.o.b. Mines, on the Columbus Market of Bituminous Coal from the Hocking District.

German Coal Industry Seeks Way Out of Debris of Ruhr Blockade

Buried in Most Momentous Situation Ever Evoked by Coal Mining —
Fear Felt of Probable Partition of Ruhr and Rhineland —
Await Process of Deflation

By H. O. HERZOG
Berlin, Germany

The reviewer of the German coal situation in 1923 is greatly handicapped by lack of authentic data. Official information ceased to be compiled at the beginning of the Ruhr occupation for all of Germany. The sparse figures given out cannot be regarded as reliable, as they have been devoted to substantiate arguments and influence public opinion. In surveying the situation estimates have to be substituted.

The coal situation of 1923 was held completely under the sway of the Ruhr occupation. The latter situation came about, it will be remembered, because deliveries of fuel for reparations constantly fell short of the stipulated quantities and were deficient in quality. This at least is the official explanation, which, by the way, is not accepted in Germany, where deeper designs of the occupying powers are commonly suspected. The shortage was stated by the German side to be about 10 per cent, but it really was somewhat higher. Anyway, experience since then has proved beyond doubt that the quantity of fuel by which Germany was in default was insignificant in relation both to total output and consumption and could have played no part of any importance whatsoever with regard to German needs. The sinister consequences of the Ruhr occupation to the German state are now common property. This is no doubt the most momentous issue in history which coal has evoked.

After the detachment of Upper Silesia and the Sarre district but prior

to the occupation of the Ruhr, the remaining fields' contribution to the total production was as follows:

	Per Cent
Ruhr.....	79.0
Left bank of Rhine.....	5.2
Upper Silesia.....	7.8
Lower Silesia.....	4.4
Saxony.....	3.3
Other parts.....	0.3

During the first months of the occupation the Ruhr mines continued operations at an undiminished rate, hopeful of an early settlement and trusting that the Franco-Belgian engineering mission would not be able to remove the fuel produced. When these hopes failed to materialize operations were restricted to such quantities as could be disposed of immediately. This strategy was maintained until traffic came to an almost complete standstill, all available storing space occupied.

Beginning in April restriction was placed on extraction and coke production, which in June resulted in a nearly complete shutdown of operations. Only the mines under contract to Holland and Switzerland and engaged in reparations supply to Italy continued at work, hampered however, by transportation difficulties. Production of by-products was continued at a reduced rate. Still the situation did not become precarious until the metallurgical works were deprived of their supply of fuel. The growing unemployment resulting therefrom, which spread over nearly all lines of industry, together with the enormous strain it caused upon the state finances, was responsible for the ultimate collapse of the passive resistance.

RUHR OUTPUT DROPS 90 PER CENT

The output of the Ruhr in 1923, which in January was still 100 per cent, or even more, of the 1922 average, dropped step by step to about 10 per cent at the end of the year. The average was in the neighborhood of 30 per cent. The Ruhr mines outside of the occupied zone produced about 6,000,000 tons of coal and 1,500,000 tons of coke. The total Ruhr production in 1923 may be estimated at 36,000,000 tons instead of 93,788,000 tons in 1922 and 91,006,000 tons in 1921. The shortage compared with last year is about 58,000,000 tons.

In the other districts operations were carried on through the whole year, disturbed, however, by frequent strikes, passive resistance of the workers and impaired by a generally reduced rate of efficiency. The 36,177,000 tons produced in 1922 outside of the Westphalian basin dropped in 1923, by a safe

estimate, to 30,000,000 tons. If these estimates are accepted, the total German production of bituminous coal in 1923 compared with previous years was as follows:

	Metric Tons
1913.....	190,109,000
1921.....	136,227,000
1922.....	129,965,000
1923.....	66,000,000

It is quite impossible to gain any insight on production of coke. In 1913 it was 36,630,000 tons; in 1921, 27,913,000 tons, and in 1922, 29,664,000 tons. In 1923 the production could hardly have exceeded 13,000,000 tons, of which about 5,000,000 tons was contributed by the Ruhr.

BROWN COAL OUTPUT ALSO SAGS

Brown coal production increased greatly during the first months of the Ruhr occupation, but the declining market in the second half of the year caused a marked reduction of output. The Rhenish brown-coal basin, which was drawn into the vortex of the Ruhr blockade, deprived of part of its market, suffered from a regular glut. All in all brown coal production in 1923 was at least 10 per cent behind the 137,207,000 tons of 1922. The estimated production of 120,000,000 tons of brown coal is equivalent to about 28,000,000 tons of bituminous coal.

In view of the possibility of Ruhr and Rhineland becoming detached from Germany as a separate state, it is of interest to ascertain the distribution of coal reserves which would result therefrom. The following figures present a survey in this respect:

	Metric Tons
Germany's reserves in 1913.....	410,000
Lost to Poland.....	146,000
Lost to France (Lorraine).....	800
Sarre district.....	15,700
Total.....	162,500
Remaining to Germany.....	247,500

The remaining reserves are situated as follows:

MOVEMENT OF COAL PRICES COMPUTED IN GOLD MARKS (PRE-WAR PARITY)

Occupied Rhineland.....	10,500
Occupied Ruhr.....	195,400
	205,900
Unoccupied Ruhr.....	18,200
All other interior parts.....	23,400
	41,600

In the event of such partition the German interior would retain only about 10 per cent of the coal reserves within German frontiers in 1913.

Coal prices in 1923 showed an almost unbroken upward flight. They were changed in ever shortening intervals, at times even weekly. Toward the end of the year they were placed on a gold basis, at which after a few violent convulsions, they remained stable. The paper mark movement of prices showed strong fluctuations. At first it followed the vagaries of the mark rate in the proximity of pre-war prices, always, however, with a marked tendency to rise beyond. In the course of the year this tendency became so pronounced that the coal tax had at first to be reduced to three-quarter and later on was abolished entirely. The price movement is illustrated by the accompanying diagram which compares the prices for Ruhr fat run-of-mine, in 1914 with 1923. The prices have all been reduced to their pre-war gold equivalent at the mark rate prevailing when the prices came into force. The wild jumps, even of the gold equivalent of prices, makes this an interesting record.

PRICE CONTROL BREAKS DOWN

The break-down of the control of coal prices carefully preserved during post-war years was caused by a number of circumstances, foremost of which were the growing dependency on imports, the rapid mark depreciation, the greatly increased price level of mining material and, lastly, the labor situation. At the end of 1923 prices were double the pre-war level.

Most remarkable among the several surprises which the Ruhr occupancy afforded was the fact that an actual shortage of coal in the German interior did not result. The visible supply remained at all stages behind the commonly assumed average of con-

sumption. Still the scarcity, such as there was, was kept within moderate limits. Temporary shortages occurred at various times, confined, however, to certain locations and caused rather by deficiencies of transportation than by lack of supply.

The explanation is to be found in the fact, revealed soon after the beginning of the Ruhr blockade, that the stocks of fuel on hand far exceeded all estimates. Large quantities of fuel had been rushed from the Ruhr to the interior as long as the frontier was open. While these shipments materially increased the stocks in hand, they were of course insufficient to balance the shortage of fresh supply during five or six months.

SUPPLY AND DEMAND RULE AGAIN

When the stocks of fuel were exhausted and the market was closely approaching a hand-to-mouth condition, the decline of industrial activity and stinted consumption caused by the enormous rise of prices quickly restored the equilibrium of supply and demand. Consumption dropped to a level without precedent. Whereas during the first months of the year all mining districts of the interior, working under high pressure, could not cope with the demand, toward the middle of the year a state closely resembling overproduction was reached. The decline became noticeable as early as April. In the subsequent months only coke and brown coal briquets continued in brisk demand. In July, however, a complete calm settled upon the market, lasting without a break until the end of the year.

Imports of coal reflect the decline of consumption but to some extent only. During the first months of the year all efforts were made to obtain as much foreign coal as possible and as finances permitted. Contracts were closed for months ahead. In May, buying on a large scale was stopped and efforts were made to cancel or reduce running contracts. The sharp drop of the market is evidenced in the curve of imports in a much slower decline. Besides, the import continued at a certain

extent even in the face of a pronounced slump on the market of domestic coal, because the latter could not substitute Ruhr coal quality.

The following figures show coal imports from January to September, 1923, the latter month being the last for which foreign trade returns had become available at the end of the year. The corresponding figures of 1922 are added for comparison. The period mentioned coincides with the duration of the Ruhr occupancy, and therefore its effect on importation is reflected.

GERMAN IMPORTS OF COAL, JANUARY-SEPTEMBER, 1923 AND 1922
(In metric tons)

	1923	1922
January.....	1,870,127	194,078
February.....	1,421,832	162,735
March.....	3,397,658	284,979
April.....	2,920,097	336,921
May.....	2,495,649	333,704
June.....	2,977,179	789,799
July.....	2,286,010	1,542,223
August.....	2,280,952	1,721,173
September.....	1,601,913	1,815,036
Total.....	20,311,996	7,180,647

The zenith of imports was reached in March. Comparing the figures of 1923 and 1922 it would seem that about 13,000,000 tons represents the total import increment due to the Ruhr occupancy. There is, however, a doubtful element in this conclusion. It leaves out of consideration the fact that in the six months preceding the Ruhr occupation imports had reached an average of 1,750,000 tons per month. The monthly average of January-September, 1923, was 2,250,000 tons. On the basis of the former the increase of the latter would appear to be only 500,000 tons per month. It must be supposed that the Ruhr occupation was considered in Germany an inevitable fact and preparation for it made long before it took place. The only feasible explanation seems to be that the sharp rise of coal imports in the second half of 1922 was part of the program to accumulate reserves for this event.

The following figures show imports of coal and byproducts in January-September, 1923, in comparison with the corresponding period of 1922, in metric tons.

Southern Appalachian. PERCENTAGE OF FULL-TIME OPERATION OF COAL MINES AND TIME LOST BY CAUSES

	1923	1922
Bituminous coal.....	20,311,996	7,180,647
Brown coal.....	1,183,352	1,751,948
Coke.....	1,074,673	1,781,090
Patent Fuel { bit. coal.....	121,340	14,227
brown coal.....	44,548	29,661
Coal tar.....	10,772	24,017
Pitch.....	11,421	18,411
Light oils.....	18,014	1,627
Heavy oils.....	6,401	508
Naphthalin.....	2,135	561

With regard to countries of origin, Great Britain is first by a wide margin, Polish Upper Silesia following. The respective figures are, in metric tons:

	1923	1922
Great Britain.....	12,076,847	4,957,488
Polish Upper Silesia.....	7,235,043	984,486
Sarre district.....	103,680	814,672
Czechoslovakia.....	652,959	101,654
Other countries.....	243,466	322,348

Of the 1,074,673 tons of coke imported 745,446 tons was of British origin, 139,900 tons came from Polish Upper Silesia and the rest from other countries not specified.

The export of coal and byproducts in January-September, 1923, in comparison with the corresponding time of 1922 was as follows, in metric tons:

	1923	1922
Bituminous coal.....	841,703	4,675,186
Brown coal.....	5,083	11,732
Coke.....	197,042	729,726
Patent fuel { bit. coal.....	14,338	37,968
brown coal.....	196,431	299,957
Coal tar.....	14,409	15,158
Pitch.....	14,568	56,926
Light oils.....	914	4,326
Heavy oils.....	27,284	97,161
Naphthalin.....	3,170	2,958

Alaska Coal Output Jumps 25 per Cent in 1923

In 1922 Alaska produced 79,000 tons of coal from twelve small mines and in 1923 about 100,000 tons from the same number of mines, according to the U. S. Geological Survey. The largest quantity came from the Evan Jones mine, in the Matanuska field, and the Healy River mine, in the Nenana field, both served by the Alaska R.R. The significant feature of the year is that the territory is supplying more and more of its own fuel.

Though some exploration of the high-grade coal of the Matanuska and Bering River field was continued in 1923, it has not yet been proved that these fuels can be mined cheaply enough to find an export market. Meanwhile evidence of the enormous reserves of lower grade bituminous and lignitic coals in Alaska is accumulating each year. S. R. Capps reports the finding of workable beds of coal carrying about 60 per cent of fixed carbon at Mile 341, on the Alaska R.R. This coal, which has been opened up, occurs in the Cantwell formation (Eocene), which is widely distributed in this region and long known to carry small seams of coal, but this is the first bed found that has been proved to be of commercial value. The bed mined is from 5 to 6 ft. thick. The discovery of the bed itself is significant, as it is easily workable and quite accessible. Of possible greater significance is the proof of the presence of a new coal-bearing formation near the railroad.

Though the development of Alaska's

The chief countries of destination of coal and coke exports were Holland, Czechoslovakia, Switzerland and Austria.

The situation at the end of the year, three months after the end of the Ruhr blockade, is greatly involved and very precarious. Business is still ebbing and no turn of the tide is in sight. The retrogression of prices, from the exorbitant level they reached during the last excesses of inflation, which put German industry completely out of business for the time being, is a slow and tedious process. No decided revival of the coal market can be hoped for until this process is completed.

GLOOMY OUTLOOK FOR 1924

The bold experiment of rebuilding a gold currency without a gold basis is yet untried. Confidence is lacking. In consequence a dangerous unstability of basic conditions prevails. The outlook for this coming year is therefore gloomy in the highest degree. Moreover, the fate of the Rhineland and the Ruhr is hanging in the balance. Developments point in the direction of a gradual but inevitable alienation of these two provinces. The consequences of their ultimate detachment would be quite impossible to forecast. The understanding arrived at between the Ruhr mines and the Interallied Mission of

Control also is more in the nature of an experiment, compelled by the force of circumstances rather than a well-considered action. It remains to be seen, whether the coal industry of the Ruhr can carry the enormous burden it involves.

The only gleam of light visible at the advent of the new year is the labor situation. The resistance of the miners and the labor element in general to the return to pre-war condition, assisted by a regular tidal wave of unemployment, apparently has been broken. The re-establishment of pre-war labor conditions seems to be on the way. It is impossible, however, to overlook the fact that the acquiescence of the working classes is not due to any change of mind in the matter of their much cherished so-called revolutionary achievements but rather to the fact that, labor funds having been swept away by the vortex of inflation, labor has no hope of defending them effectively in a drawn-out struggle.

The end of 1923 finds the German industry trying to hew a way out of the heap of debris under which the great landslides of the year nearly buried it. This road is strewn with a great number of "Ifs" which defy forecast. Only the great vitality still remaining in the people supports the belief in ultimate success.

high-grade coal has thus far been disappointing, there are vast coal reserves of less fuel value in the territory, and a considerable percentage of these has been made accessible by the government railroad. There can be no reasonable doubt that these reserves will eventually be drawn upon to supply the growing population of the Pacific seaboard.

There are enormous areas of coal-bearing formations in northern Alaska, though most of them are now too inaccessible to be utilized. William T. Foran, of the U. S. Geological Survey, who last summer explored the Arctic littoral between Cape Beaufort and Wainwright Inlet, found evidence of a northern and inland extension of the Corwin coal beds.

Mr. Foran found some gently folded coal beds on Kukpowruk River, five or six miles from the coast, which dip from 20 to 40 deg. and are not broken. Some thirteen beds were seen, 4 to 10 ft. thick. Though not yet analyzed, these coals appear to be of the quality of the Corwin coals, which are sub-bituminous. This part of the Arctic coast is accessible to vessels from two to three months, and it af-

fords better shelter than that at Corwin. These coals, which probably are of the Jurassic age, might be utilized to supply Nome and northeastern Siberia.

Shipments from Duluth Drop

Shipments from Duluth-Superior docks suffered a falling off during the past year, according to figures made public last week by the Duluth dock authorities. These figures show that during 1923 199,503 cars went out from the local docks, as compared with 245,683 cars in 1922. This falling off in shipments, coupled with the largest receipts in years, leaves large stocks on the docks. Only continued cold weather will assure a clean-up before spring.

News Of the Industry

No Bituminous-Coal Dictator—Yet; Industry Can't Afford Big Salary

The bituminous coal industry, for the present at least, is not to have a dictator. This was decided definitely at a meeting of the Board of Directors of the National Coal Association in Washington Jan. 8 and 9. The reason given for the action is that the industry cannot afford to pay such salaries as are received by Will Hayes and Judge Landis. There are some who see in this nonchalant dropping of the proposition that had been so stoutly urged a few months ago the passing of the crisis which loomed then.

The directors paid a high tribute to John C. Brydon, president of the association, and expressed their deep appreciation of the sacrifices he has made to further the welfare of the industry. Harry L. Gandy, the executive secretary, was instructed to relieve Mr. Brydon of as much work as possible in the future, so that the demands on his time would be less exacting.

President Brydon was authorized to name several committees. One of these committees is to confer with a similar committee of the American Mining Congress and to study Senator Oddie's bill providing for a Department of Mines. Another committee is to study the practicability of establishing coal exchanges. Still another committee is to be named to prepare resolutions expressing the sorrow of the directors occasioned by the death of Julian B. Huff, of the Keystone Coal & Coke Co., of Greensburg, Pa.; R. M. Randall, of the Consolidated Coal Co., of Michigan, and of Kuper Hood, of the Houston Coal Co., Cincinnati.

The time and place of the annual meeting are to be determined by an-

other committee which Mr. Brydon is authorized to name.

C. E. Bockus, D. B. Wentz and another member to be chosen were designated as the National Coal Association's representatives on the committee which is to act in an advisory capacity to the coal division of the Department of Commerce. The American Wholesale Coal Association and the National Retail Merchants' Association already have designated the three members which each association was asked to select for service on that committee. For service on the committee in the absence of the members, three alternates will be chosen. The anthracite operators and the railroads also are to be represented on the committee.

The railroad relations committee is to be known in the future as the transportation committee. George C. Eastwood, general manager of the Consolidated Coal Co., of Saginaw, was elected a director to fill the unexpired term of R. M. Randall.

Whether or not the association will print an annotated edition of the report of the Harding Coal Commission will be decided when enough members have indicated their desire to purchase the book, at cost, to justify its printing.

The Board of Directors of the association unanimously adopted the following resolution regarding taxation at the quarterly meeting:

"Whereas, A strong expression of opinion coming from members of the National Coal Association, located in the twenty-nine bituminous-coal producing states, is to the effect that the present system of federal taxation is seriously interfering with the re-estab-

lishment of stable and prosperous industrial conditions in the country, and

Whereas, the condition of the times requires the greatest possible reduction in taxes for all classes, therefore Be it resolved, That we favor a curtailment of governmental expenditures and a much needed reduction in taxation so that capital, instead of finding its way into tax-exempt securities, will seek investment, resulting in industrial expansion."

Twenty-six of the thirty-six directors were present. Six of the ten who were prevented from attending were represented.

Commends Coal Commission's Handling of Complex Job

Commenting on the report of the Harding Coal Commission, Richard T. Ely, a widely known economist, says:

"The complexity of the problems in mineral lands is illustrated by the recent investigation by the U. S. Coal Commission. While there are those who are expressing themselves as dissatisfied with the reports of this commission, it is generally conceded that its work is commendable because of the commission's effort to get at the economic as well as technical facts regarding this one industry.

"Pressing problems of a complex nature have resulted from the rapid growth of the mineral industry and we cannot expect to wave a wand and correct all ills.

"In the past, much effort and time have been spent in solving the technical problems of the industry, and in the solution of these rapid progress is being made. The economic aspect of the problems has been neglected to a great extent, but the time has come when more attention must be paid to these."

Daugherty Would Forbid Dissemination of Trade Data by Associations

In "Informal Correspondence" Says He Sees No Objection to Collection of Statistics by Organizations, but Would Put Distribution in Hands of "Responsible Medium"

Another chapter in the history of trade-association activities was added last week, when there was released another batch of correspondence between the Secretary of Commerce and the Attorney General. Mr. Hoover asked Mr. Daugherty whether the Department of Justice interpreted the consent decree in the Tile case as a prohibition to trade associations co-operating with the Department of Commerce from distributing tabulations among members. That, it will be remembered, was one of the things prohibited in the Tile decree. Mr. Daugherty replied that that is just what he meant and added much about trade associations and collection of statistics in general.

The letter of the Attorney General to Mr. Hoover says that it is a fallacious idea that just because data collected by associations relate to past and closed transactions, there can be nothing illegal about such collection. It is further stated that it is a fallacy to conclude that just because the figures collected are given to the public in any form, no matter how thoroughly, the transactions are legal by reason of such publicity.

When asked for an expression of opinion as to the correspondence between Secretary Hoover and Attorney General Daugherty, Judge Nathan B. Williams, associate counsel of the National Association of Manufacturers, said:

"It is sincerely to be regretted that on a question of vital public policy, interesting alike to the business community and all who buy or consume the products of our industry, the Secretary of Commerce and the Attorney General of the United States engage in 'informal' letter writing. This extensive correspondence makes slight, if any, contribution to the clarification of the law concerning the statistical activities of trade associations.

"Apparently, legitimate trade associations will continue their statistical and other activities without reference to this 'informal' correspondence; they will not transgress the well-known inhibitions of existing law, in that they will not misuse their statistical or other trade information in promotion or furtherance of any agreement or conspiracy to fix prices, limit production, restrict sales, divide territory, or otherwise restrain lawful competition in commerce; and it appears likely that they will decline to supply any of such information to any department of the government except that which may be called for by statute under the provisions of the laws providing for the taking of the decennial and other censuses."

Secretary Hoover's letter of Dec. 11

to Attorney General Daugherty was, in part, as follows:

"Some time ago I realized that the carrying out of the purposes of this department as set forth in the organic act 'To foster, promote and develop a foreign and domestic commerce, the mining, manufacturing, shipping and fishing industries, and the transportation facilities of the United States,' required that the character of information desired, and the gathering of it from the individual units of industry would involve such a gigantic physical task that this department with its facilities could not undertake such action with the faintest hope of attaining the ends desired. I therefore have in the past utilized to a very considerable extent the trade associations as a medium for securing such information and have received splendid co-operation from them as a whole.

"Seeking to clarify the situation regarding legitimate trade association activities, I set forth my views in several letters to you in February, 1922, and requested your informal opinion as to the legality of many association functions, including the collection and distribution of the character of information herein referred to. Predicated principally upon your informal views in reply thereto, this department formulated a plan of co-operation with trade associations under which the association's secretary collects and compiles unidentified current information and distributes it to the members simultaneously sending identical reports to governmental agencies, competitors of the association's members, and to any other person who arranges for them. Under this plan no supplemental or separate reports are transmitted to the members only. This department receives all such reports for wide dissemination by publication.

"My attention has been directed to a decree entered Nov. 26, 1923, in the District Court of the United States for the Southern District of Ohio, in the case of United States vs. Tile Manufacturers Credit Association, et al, paragraph two of page four of which is as follows:

Provided, however, that the defendants are not restrained or enjoined from maintaining an association, either voluntary or incorporated, for the following objects and purposes and none other.

after which various permissible activities are set forth. Paragraph 2 of page 3 is as follows:

Provided, however, that the defendants may through the association, or corporation hereinafter provided for, receive and compile for transmission to any governmental agency such information and statistics as it may request as to the production, shipments, the stocks on hand and the prices of tiles, but are restrained from distributing said information among them-

Wide World Photos.

Harry F. Bovard

Mr. Bovard, who lives in Greensburg, Pa., was recently elected president of the Keystone Coal & Coke Co., the largest producing company in Westmoreland County, succeeding Julian B. Huff, who died in Philadelphia Dec. 23. Thirty-two years ago Mr. Bovard became a clerk in the employ of Coulter & Huff, predecessors of the Keystone company, whose coal operations were the first in the Greensburg basin.

selves, except that information respecting sales may be collected annually and used to enable the assessment of the several members for their proportionate parts of the several expenses of the association, and for no other purpose.

"I interpret the last quoted paragraph to mean that it would be unlawful for the proposed association on behalf of its members to transmit information and statistics of the character therein described to its members, but that it could receive and compile it for the purpose only of transmitting it to a governmental agency that might so request.

"It is my understanding that this decree is only binding between the parties thereto; however, in view of informal conversation between representatives of your department and this department on the subject of trade-association activities, I am inclined to be of the opinion that the last-mentioned paragraph embodies an expression of the present policy of your department relative to the collection, compilation and distribution of information and statistics of the character therein set out applicable to trade associations in general.

"It is not the desire or purpose of this department to continue operations under the co-operative plan if it is in conflict with the policy of your department; it is our desire, however, to call your attention to the situation that in my opinion will develop, if my interpretation of this decree correctly expresses the policy of your department.

"I think there is great likelihood that not only the associations from which this department now receives valuable statistics but a great many others will

discontinue the collection of information and statistics as to production, shipments, stocks on hand and the prices on closed transactions. They will not go to the expense of collection, if the only use that can be lawfully made of them is to transmit them to some governmental department. If this should happen, I fear that the efficiency of this department in carrying out the purposes set forth in the act creating it would be very greatly impaired.

"I respectfully request that you informally advise me, in view of the foregoing, whether or not this department should discontinue its present plan of cooperation with trade associations."

MR. DOUGHERTY'S INFORMAL REPLY

Replying under date of Dec. 19, 1923, Mr. Daugherty wrote in part as follows:

"You will observe that this proviso in the decree complies strictly with the paragraphs above quoted from your letter of Feb. 3, 1922.

"Two objects were had in mind during the conferences which preceded the above-mentioned correspondence, both of which it was thought were secured by the limitations embraced in the above quoted paragraphs of your letter: First, that the information distributed should be general, and, second, that individual contact between those engaged in the same industry with reference to matters which vitally affect prices should be avoided. If the character of the information and the manner of its dissemination be restricted as specified in your letter, one member would not be informed as to the individual activities of another member, and those engaged in the industry would be prevented from revealing their business to their competitors.

"Under the system now practiced by many of the associations each member reports its production, shipments, stocks on hand, and each individual sale, stating the price at which it is made and, generally, the locality where made; and this information is distributed by the secretary or manager of the association among all the members, though in some associations the names of the members making the sales are omitted. Thus each member reveals the details

Wooden Coal

Out West they used to burn buffalo chips, cobs, hay, corn and whatnot instead of coal, but these things hardly were ranked as fuel "equal to anthracite." The latter claim, however, is made for pressed sawdust briquets, now being manufactured in the State of Washington. It is announced that tests show this "wooden coal" to be 97 per cent carbon, 2 per cent volatile and 1 per cent ash. It can be briquetted for \$6 a ton, according to those interested. The enterprise would depend upon the great waste piles of sawmills for its raw material.

of his entire business to every other member, which, as suggested by the Supreme Court in the Hardwood case, is entirely inconsistent with the normal attitude of real competitors.

"In my judgment the effect of general information as to the conditions of an industry, such as the total production, shipments, stocks on hand and the average price, or range of prices, is entirely different from that resulting from each person engaged in an industry receiving directly, or through a common medium, reports which reveal to him the exact condition of the business of all of his competitors. When thus informed each one is invited, and is naturally inclined, to imitate the conduct of his most successful competitor; and the spirit of comradeship created by the confidential exchange of information of this character necessarily prevents the free competition between them which would otherwise prevail.

"Those who organize and conduct these associations appear to entertain the idea that if the information imparted relates only to past and closed transactions there can be no violation of the Anti-Trust Act. In my judgment such an idea is wholly fallacious. One's future conduct is to be judged by what he has done and is then doing, and not so much by what he says he will do. It is one's actual conduct that is taken as an example for imitation.

It has developed in the trial of cases involving associations that the members first agreed-upon prices; but such a plan did not work because the members could not be relied upon to keep the agreement; and the system of exchanging statistics was adopted because it was found to be the only effective way to procure co-operation as to prices and production; and such co-operation could be thus procured even in the absence of any positive agreement.

"Again, the idea seems to be prevalent that no exchange of information between the members, regardless of its extent or character, can be unlawful if at the same time publicity be given thereto through the press or some governmental agency. In my judgment this idea is likewise fallacious. The illegality as well as the evil results arise from the co-operation among the members pursuant to a positive or tacit understanding; and this co-operation is not affected by publicity. Those who purchase the commodity, though fully informed as to the activities of the association, can protect themselves only by an organization and co-operation of like character, which, if it were lawful, is an impossibility upon the part of the public.

"I have no doubt that it is important that those engaged in an industry have general information as to the conditions of that industry, but I think that information should be distributed strictly through a responsible medium, like your department; and I see no objection to its being gathered by an association provided it be strictly guarded and the association be prohibited from distributing it among its membership. This is the same view that I entertained when the communications were exchanged in February, 1922; and it has since been strongly confirmed by decisions of the Supreme Court, and by investigations of a number of associations and the trial of cases involving associations.

"This is but a statement of the position I feel impelled to take as Attorney General of the United States in enforcing the Anti-Trust Act. But, of course, as to what activities and how far you will co-operate with trade associations are matters for your determination in conducting your department."

Midwest Retailers Decide Not to Split From Their National Association

Instead They Appoint at Chicago Meeting Half of East-and-West Committee on New Policy—Hear Proposals for Coal Exchange and for National Coal Institute

Coal men representing the most important retail interests in the Middle Western States decided at Chicago on Jan. 12 not to withdraw from the National Retail Coal Merchants' Association, although a considerable number of them went to the meeting frankly favoring the creation of a separate Midwest retailers' group. Instead they spent the entire day debating with some heat various problems over which there has been difference of opinion as between East and West, and the evening listening to plans for a coal exchange and a national coal institute, and finally chose a committee of eight which will meet a committee to be appointed by Samuel B. Crowell, president of the National, to represent the Eastern groups of the association. This body is expected to report at the next national convention in Bluefield, W. Va., in June, various changes in the policy and program of the National that will make that body stronger and of more complete service to all sections of the country.

The eight Westerners on the committee are Marshall Keig and Ashley Miller, of Chicago; Ely Barkhume, of Detroit, Mich.; R. H. Jones, of Kenosha, Wis.; H. L. Laird, of Minneapolis, Minn.; Frank G. Laird, of Indianapolis, Ind.; H. S. Mitchell, of Kansas City, Mo., and R. D. Kelly, of Springfield, Mo.

During the day the Midwesterners, who were in session at the invitation of the Chicago Coal Merchants' Association, passed resolutions favoring the Mellon plan of tax reduction and favoring the House bill introduced by Representative Dyer, of Missouri, aimed to reduce the loss of coal caused by theft in transit, by stiffening the penalty for such theft.

John R. Mauff, a member of the Chicago Board of Trade, which operates the grain-trading mart of that city, spoke at a banquet of retailers and producers on the proposed creation of "The United States Coal Exchange," which he would like to see the coal trade set up. He has had much experience in creating such exchanges in various industries. The last venture was in paper—an exchange which did not survive in its original form because of too great diversity of interests.

Mr. Mauff's plan would draw together producers, sellers and buyers of coal on a membership basis like that employed in any other trading exchange. It would bring coal trading into the light of day—in raucous voices—with much benefit to the industry, he thinks. It would be intended to protect the coal trade from "unjust and unlawful exactions," to diffuse accurate

and reliable information among members, to produce uniformity in contracts and the customs of coal trading, to settle differences between members, to provide standards of quality and other such advantages.

Mr. Mauff would have the exchange accept the best known grades of coal as setters of basic prices "with other grades established at a differential higher or lower according to quality and the actual scientific and demonstrated monetary difference in values existing from time to time." He would have a statistical service broadcast the statistics of the market and a daily report go to all members showing sales and shipments. He denied that the exchange would replace coal men's associations, pointing out that the grain exchange in Chicago has not dissolved the several associations of its members. In fact he believes, in view of Attorney General Daugherty's recent ruling against the compilation of trade statistics by associations, that an exchange is the only legal vehicle by which such compilations and reports could be made.

President Crowell of the National association, described the "National Coal Institute" which the retailers' national association would like to see created. It would be a bureau equipped to make various studies of all manner of fuel problems from a scientific and more or less disinterested viewpoint. Such an institute should aid the coal industry in the defence against oil, it should educate the public concerning coal, through publicity and other channels, in a way that has never been so much as approximated, and should serve as a valuable contact between coal producer, coal seller and coal consumer.

"For a good many years," said Mr. Crowell, "I have been thinking—dream-

ing would be a better word—of a day when the coal industry, all branches of it, would be united in a great co-operative movement for its own betterment and the better service of the public—the awakening of public opinion to the fact that we coal men are in reality decent citizens and not rascals. Recent happenings would seem to indicate that there is a possibility of my dream coming true.

"Most of you probably are aware that the anthracite operators have opened in Philadelphia what they call a Coal Economy Show. They have gone to great expense and have spared no pains to interest the public in this show, which is the first of four similar exhibitions to be opened within the month in the principal cities of the East. Primarily, these shows are designed to create a domestic market for the small sizes of anthracite, but the Philadelphia exhibition is having a much wider influence. It contains a mass of valuable information concerning the production and distribution of anthracite and the producing companies have detailed the best men among their engineers and fuel experts to explain the exhibits and advise consumers regarding various heating problems.

"One of the principal features of the show is the handling of complaints made by disgruntled consumers. This is done through the co-operation of our retail organization, the Philadelphia Coal Exchange. Complaints regarding quality, received at the show, are referred to the Exchange. We send an impartial investigator, employed by the organization, to look into the complaint, which usually has to do with quality; we take care of correct weights ourselves. If the fault lies with the dealer—if he has made a bad delivery—we get after him. If the fault lies with the shipper the operators get after him. The system is by no means perfected yet—it has been in operation only a little more than two weeks—but the point I want to emphasize is that it marks the beginning of closer co-operation between dealers and producers and the beginning of the end of the ancient and profitless system of buck-passing between these branches of the industry.

"The effect of this attempt at co-operation with the public and the endeavor to adjust disputes is seen in the changed attitude of the Philadelphia newspapers, which heretofore have been merely passive where they were not openly hostile. Now, without exception, they are saying nice things about the anthracite industry.

"I believe that the co-operative spirit is more in evidence in the retail coal trade than anywhere else in the industry, but it is mainly co-operation among ourselves. What I want to see and what must come about if the industry is to assume before the public and the politicians the position to which its importance entitles it, is not merely co-operation between retailers, or wholesalers, or producers as such, but the

Oiling St. Louis

A study of oil competition with coal made in and around St. Louis, Mo., awakens many coal producers whose natural market is in that territory to the fact that during 1923 the number of oil burners in the region grew from 200 to almost 3,000. It is estimated that each has replaced 25 tons of coal per year, which means "no market" for 75,000 tons in total. The local retailers' association of the region is running an advertising campaign in defence of coal though a great many dealers have taken on an important side line and now sell both coal and oil from the same yard.

broadest kind of co-operation of all branches, one with another.

"Much can be accomplished to this end through the national associations. We have ours, the wholesalers have theirs and so have the producers. We should use these organizations to the fullest extent in an effort to co-ordinate the entire industry into a harmoniously working body.

"Let us, therefore, proceed to mend our own fences in a spirit of harmony as between the various branches of the trade. And in doing so I ask you to keep in mind the goal which is my dream—a broad co-operative organization of coal men, a coal institute if you like—to which everybody, public, coal men and, if you will, politicians, may turn for information and advice on every subject connected with fuel, freely given by men of recognized ability whose words will be accepted as authoritative; an organization the very character of which will eventually place the industry where it belongs in the public mind."

At the banquet the National Association presented a grand piano to Homer D. Jones, of Chicago, former president for a year. John Lloyd, of Philadelphia, was toastmaster. Charles M. Moderwell, of Chicago, a veteran operator and wholesaler, in a brief speech warned the retailers that the coal industry must pull together or "something unpleasant is going to happen to us."

Kansas Governor Finds Coal Prices Lower

The usual winter protests on coal prices have been reaching Governor Jonathan Davis, especially from Topeka, Lawrence and Emporia. He insisted somebody should investigate. All state departments that might logically make such a quiz asserted that they were too busy. So Governor Davis made the Industrial Court judges assistant attorneys general. Finally Judge John J. Crawford reported that in Topeka prices are from \$1.25 to \$1.75 lower than last year with no changes in freight rates. He said that Illinois producers, with thick coal, are making a drive to take the Missouri Valley markets with prices too low for Kansas and Oklahoma producers to meet, in spite of their short-haul advantages.

R. M. Randall

Mr. Randall, who died at Battle Creek Jan. 1, was a man of varied interests, having been a banker and lumberman as well as general manager of the Consolidated Coal Co. of Michigan. He also was a director of the National Coal Association.

Conclude Argument in Maynard Case

Concluding arguments in the case of the Maynard Coal Co. against the Federal Trades Commission were presented to the Court of Appeals of the District of Columbia Jan. 10. The case was argued by Mr. Basic, attorney for the Trade Commission, and by former Judge Stephen A. Foster, of Chicago.

In his argument Mr. Basic contended that in demanding cost of production data the commission was merely seeking information from the coal industry, while Judge Foster insisted that the commission in doing so was trying to regulate the industry.

At the request of Mr. Basic, the commission was permitted to file with the court the brief of the Solicitor General of the United States filed in the U. S. Supreme Court in the Claire Furnace case.

The indications are that the Court of Appeals will not render a decision in the Maynard case until after the U. S. Supreme Court decides the Claire Furnace case.

Daily Byproduct Coke Output Slightly Lower Last Month

The daily rate of output of byproduct coke declined slightly during the last month of 1923. While the total output of byproduct coke was somewhat greater than in November—2,999,000 tons against 2,942,000—the output per day decreased from 98,055 tons to 96,740 tons, a decline of 1.3 per cent. The percentage of production to capacity declined from 81.1 per cent to 80.1 per cent. There was no change in the number of plants active; out of 70 byproduct installations now in existence, 65 were in operation and 5 were idle.

The total production of the beehive ovens in December was 1,063,000 tons, a decrease of 40,000 tons compared with November. The output in December, however, was reduced by the Christmas holiday and by the occurrence of five Sundays in one month, and the rate of production per working day underwent no change.

MONTHLY OUTPUT OF BYPRODUCT AND BEEHIVE COKE IN THE UNITED STATES (a)
(In Thousands of Net Tons)

	Byproduct Coke	Beehive Coke	Total
1917 Monthly average	1,870	2,764	4,634
1918 Monthly average	2,166	2,540	4,706
1919 Monthly average	2,095	1,638	3,733
1920 Monthly average	2,565	1,748	4,313
1921 Monthly average	1,646	462	2,108
1922 Monthly average	2,374	669	3,043
October 1923	3,099	1,290	4,389
November, 1923	2,942	1,103	4,045
December, 1923	2,999	1,063	4,062

(a) Excludes screenings and breeze.

In spite of this gradual decline in the output of coke, the ovens continue to require very large quantities of coal. To manufacture the coke produced in December required the charging of 5,986,000 tons of coal, of which 4,309,000 tons was used by the byproduct ovens alone.

ESTIMATED MONTHLY CONSUMPTION OF COAL FOR MANUFACTURE OF COKE (a)
(In Thousands of Net Tons)

	Consumed in Byproduct Ovens	Consumed in Beehive Ovens	Total Coal Consumed
1917 Monthly average	2,625	4,354	6,979
1918 Monthly average	3,072	4,014	7,086
1919 Monthly average	2,988	2,478	5,466
1920 Monthly average	3,684	2,665	6,349
1921 Monthly average	2,401	706	3,107
1922 Monthly average	3,411	1,056	4,467
October, 1923	4,452	2,035	6,487
November, 1923	4,226	1,740	5,966
December, 1923	4,309	1,677	5,986

(a) Assuming a yield of merchantable coke of 69.6 per cent of the coal charged in byproduct ovens, and 63.4 per cent in beehive ovens.

Sees Nation's Economic Future Dependent On Adequate Transportation

Herbert Hoover Urges Far-Sighted Policy at Opening of National Conference—Barnes Asks Better Treatment from the Government—Hines Discusses Budget System

The formulation of long-view national policies in transportation that will effect economical and adequate handling of goods is the first fundamental to our whole economic future, declared Herbert Hoover, Secretary of Commerce, at the opening session of the National Transportation Conference at Washington on Jan. 9. Continuing, Mr. Hoover said that "the solution of the problems in such policies is only in part a matter of legislation and governmental relations. They are in large part to be solved by initiative and voluntary co-operation among the business community. It marks a great step in our business progress when all the elements such as are represented in the sub-committees may come together and agree on solutions of important questions, and outline a method of co-operation by which they may be attained."

Julius H. Barnes, president of the Chamber of Commerce of the United States, which body had arranged the conference, presided, and another speaker at the session was Walker D. Hines, former Director General of Railroads.

In his opening remarks Mr. Barnes said there should be no place for misunderstanding and antagonism between American methods in production and American methods in transportation, which have marched hand in hand to make secure the standard of possession on the western farm.

"Production, both of farm and factory," he continued, "stimulated and expanded by ready access to a great, wide market of adequate buying power, is dependent at every stage on adequacy of transportation for the enormous volume of national production. The great rising curve of living standards, the security of American health, the widening of American opportunity and the strengthening of American individual content and happiness—all these run parallel with the rising curve of the tonnage of commodity distribution. The problem is to visualize, in terms which every man can understand, the fact that transportation, adequate, ready, possessed of the means not only of present expansion but responsiveness to new methods and new devices, is the very structure on which their earning power and the possession of articles of necessity and comfort depend."

Referring to increase of industry values, Mr. Barnes said:

"It is suggestive of study when we find the increase in forms of wealth between 1900 and 1920 recorded in their major aspects as follows:

Farm values.....	281 per cent
Manufacturing industries.....	398 per cent
Railroads.....	93 per cent
Total national wealth.....	295 per cent

"The time has come when America must divest itself of the accumulated prejudices and passions in the treatment of transportation; when it must realize its dependence upon a continued and constant expansion, and plan such relations of government to this industry that it shall be able to serve the full measure of national progress."

Mr. Hines, in his address, spoke of the budget system and the proposed repeal of the rate-making rule. Of the latter proposal he said he has been able to think of but one group of the public than can find an adequate motive for advocating such a change in the law, and that is the group that wishes to see private operation fail, so as to make government operation a necessity.

Speaking of the budget system Mr. Hines said:

"We have heard a great deal in this country about a budget system and gradually the country is adopting the budget system. Section 15A is really the application of the budget principle in a broad sense to railroad regulation. The statute thus expresses the homely truth "look before you leap," and the other homely truth "count the cost." It is designed to prevent the haphazard dealing with specific rate problems without regard to the effect upon the general situation. This new railroad rule is a simple and honest recognition of the fact that the public cannot have satisfactory railroad service without paying the cost, including a fair compensation for the capital employed."

Southern Gem Coal Co. Lifts Receivership

The U. S. Court of Appeals at Chicago has lifted the receivership placed upon the Southern Gem Coal Corporation, of Chicago, by a federal court in East St. Louis. This leaves the corporation free to continue operating its various central and southern Illinois mines and other properties, including the Wabash, Chester & Western Ry., and also free to fulfill its contract to supply the output of its two Franklin County mines to Simon Levy, of Chicago, a direct-to-consumer dealer doing a big business all over the central west.

Although the East St. Louis federal court order put the property of the corporation into the hands of C. B. Thomas and W. S. Wilson as receivers, an ancillary receivership was necessary in order to give the receivers control of the books, records and operating headquarters. Without it, neither the receivers nor the corporation could produce a ton of coal. The application for this ancillary receivership was denied, Judge Wilkerson, of the District Court

95 per Cent Less Babel

A few years ago, when the Pacific Coast Coal Co. issued any notices to its employees, the communications had to be printed in half a dozen foreign languages. Today 95 per cent of the employees are American citizens and practically every one can read English, according to A. E. Holden, editor of the company's new weekly magazine for employees, *The Pacific Coast Bulletin*.

of northern Illinois, hearkening to the corporation's contention that it was now in position to meet its payrolls, interest charges and other obligations and that a majority of the creditors did not approve of the receivership. Then on Jan. 10 Judges Evans, Alschuler and Baker, of the U. S. Court of Appeals, set aside the receivership and returned the property to the corporation.

It was reported late in the week that Mr. Wilson intends at once to make a new effort to get the receivership ordered once more—this time on a basis that will make it bulletproof.

66 Convicts Mutiny in Alabama Coal Mine

Sixty-six convicts leased by the State of Alabama to the Thomas-Weller Mining Co., operating coal mines forty miles south of Birmingham, mutinied against operating methods on Jan. 11. It is reported that leaders in the strike include white prisoners who took part in the revolt at Banner mines last September, which led to a movement of state officials to better conditions under which leased convicts work in privately owned mines. The men worked in the Aldrich mines of the bankrupt Montevallo Mining Co. Officials of the company denied that any serious disturbance had taken place but did admit that the day shift had refused to work. Reports from Montevallo are that the men barricaded themselves in the slope after entering without guards. Reports that the machinery had been damaged considerably by dynamite were denied by the mine officials at the company's office in Birmingham.

Who Greeted Union with Dynamite?

It was reported from Harlan, Ky., on Jan. 8 that officials of a new office opened in that city by the United Mine Workers were greeted with a package of dynamite at the door on that date, and that the union leaders immediately left town. While it has been intimated that the dynamite was a threat, coal men believe that it may have been placed there by union men themselves, with the idea of trying to make labor feel that the operators were resisting the union idea, even to the extent of using dynamite threats.

Oddie Sifts All Coal Plans and Hearings In Drafting Administration Bill

Opposes Government Ownership and Regulation in Peace Time — Sees
Need for Encouragement and Assistance Through Mines
Department Represented in the Cabinet

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Despite Senator Oddie's desire to introduce the legislation prompted by the report of the Harding Coal Commission, it has been found that delays are numerous in attempting to frame the actual bill. It is no easy task to translate into the concise form which a bill must take the varied and intricate provisions of such a measure. While the initial bills will embody certain of Senator Oddie's ideas, which are at variance with the recommendations of the Coal Commission, it is probable that the legislation as introduced will not represent his final opinion as to what should be enacted. He is anxious to get the matter in concrete form so as to obtain criticisms and suggestions from all concerned.

The Nevada Senator, however, is not waiting for the introduction of the bill to begin work. He is studying all the different plans which have been put forward, in addition to those of the Coal Commission. He is going over the hearings conducted in previous sessions of Congress when coal legislation was proposed.

He is definitely and finally opposed to government ownership, and to the regulation of prices, profits, wages and margins in peace times. He realizes that any such enactment, in addition to being unconstitutional, would not be in the public interest. He is approaching the whole problem with the idea of obtaining an abundance of coal of good quality.

Among the things he believes will contribute to this improved service is the current publication of facts as to supply and demand, in order that both buyer and seller may act intelligently and not blindly as they did in 1916, 1917, 1920 and even during the last bituminous strike in 1922. He also would like to see gathered all facts bearing on labor disputes and upon transport, the factors which have caused interruption of supply. He thinks there should be readily available at all times facts regarding such important matters as the real earnings of mine workers and of the ability of the industry to pay. He recalls that almost all the studies of either wages or costs of production have not been so timed as to have a bearing on wage negotiations. He thinks they should be kept up currently.

The commissions which have been called together periodically to deal with difficulties arising in the coal industry soon complete the main purpose for which they were created. The facts and figures which they collect are published, but they are not kept before

the industry and the consuming public. Were there a Department of Mines, Senator Oddie argues, this highly essential information could be kept before all those concerned. The Secretary of Mines would receive from the fact-finding agency, for instance, the statistics covering quantity of coal in storage. If they should show that stocks had fallen below the margin of safety, he could urge the stocking of the approximate amount of coal necessary to provide for possible interruption.

Senator Oddie is thinking of more than an agency which will issue only bare facts. He thinks there should be in the federal government a major subdivision to which the mining industry can look for encouragement, for advice and for the formulation of policies. The current reporting of facts, however, will be only an incidental phase of his measure.

In this connection it is known that the Senator is re-reading with much interest Dr. Garfield's recommendation for an advisory committee of operators and miners to be presided over by a Cabinet member. Dr. Garfield suggested that this would be an effective means of keeping in touch with the state of the industry, its problems and its needs.

It is Senator Oddie's purpose to draft legislation in the form that does not seem to indicate that the coal industry is an enemy of the public. He recognizes it as one of the great basic industries on which the public is compelled to depend as on few others and without whose prosperity there can be no general prosperity. As a mine operator himself, Senator Oddie is in a position to appreciate the engineering achievements and the other great accomplishments that have taken place in the coal industry. He is rather impatient with the attitude of fault finding into which so many persons fall when they consider the problems of the coal industry. While he admits there is some ground for criticizing the industry, he suggests that sight be not lost of the fact that the producing power of the American miner, working with highly efficient mechanical equipment, is four times as great as that of the British or German miner and five times as great as that of the French miner.

Much has been said in condemnation of the distribution of coal. With all the faults of the existing system, Senator Oddie is rather struck with the fact that there is something to be said in favor of an achievement which involves the moving of nearly 600,000,000

tons of a bulky product from 9,000 mines to 90,000 carload buyers in 48 states.

Since our whole progress as an industrial nation depends on an abundant supply of cheap fuel, Senator Oddie feels that Congress must be careful not to create conditions which handicap the industry in the realization of maximum efficiency.

His opinion is that the federal government should play its part in creating conditions under which this great enterprise can grow and keep pace with the country's development. To accomplish this in the ideal way, he believes, calls for nothing less than a separate department with representation at the Cabinet table.

Holidays Hit Production in Central Pennsylvania

Approximately 3,480,350 tons of coal was produced in the central Pennsylvania district in the month of December, or 60 per cent of the estimated production capacity. The loadings for the last week of December showed a decided drop over the previous week, being 10,737 cars as compared with 16,664 cars the week previous.

There was a slight gain over the month of November; the December production, not including Dec. 31, was 58,466 car loads, compared with 54,695 car loads in November. The daily average production for the month of December was 2,436 carloads, as compared with 2,486 carloads in November. Prices remain the same. The number of no-bill cars in the district at the close of December was 1,034.

Working figures for the mines in the district for the last week are as follows:

Mines idle	357
Mines working 1 day	63
Mines working 2 days	64
Mines working 3 days	66
Mines working 4 days	68
Mines working 5 days	38
Mines working 6 days	0

The total production figures for the year in carloads are as follows:

January	82,835	July	73,784
February	69,297	August	80,361
March	79,542	September	67,790
April	69,567	October	63,466
May	73,768	November	57,074
June	77,416	Dec. (inc. 29)	58,466

Asks Congress to Settle For Navy Coal

President Coolidge has requested Congress to appropriate \$242,080.29 to settle judgments rendered against the United States in the U. S. District Court for the District of New Jersey and affirmed by the U. S. Supreme Court in favor of the New River Collieries Company, in which suits were instituted to recover just compensation for coal requisitioned by the Navy Department under Section 10 of the Lever Act. Judgments were rendered on April 15, 1921, in favor of the New River Collieries Company in three suits, as follows: No. 1 for \$213,100.11; No. 2 for \$19,700.91 and No. 3 for \$9,279.27.

Production And the Market

Bituminous-Coal Output Is Absorbed Readily; Spot Trade Active; Contract Movement Steady

The soft-coal market is in good condition, notwithstanding the low prices quoted. Production is easily absorbed, spot business is active and contract coals are moving in steady volume. Contracting is in the making although neither producer nor consumer appears anxious. Reported quotations for contracts range all the way from 25c. to 75c. above current spot figures at New York to from \$3 to \$3.25 at Philadelphia, with reports that a quotation close to \$1.65 had been given to a Southern railway. There also are reports that some high-grade northern West Virginia coals were being held close to \$2.75. Strike talk is having scarcely any effect on consumers, although at Pittsburgh there is a belief that there will be a suspension.

The cold wave which covered most sections of the country recently was of too short duration to have any lasting effect on the coal markets. Demand for domestic coals improved slightly, but the steam coal market was not stimulated and in the Middle West quotations softened. Domestic sizes of anthracite are easier and quotations for independent product are slightly lower. Arkansas semi-anthracite is making an impression around the Twin Cities as a substitute for Pennsylvania hard coal at \$2 less per ton.

Soft-Coal Production Recovers Quickly

Coal Age Index of spot prices of soft coal as of Jan. 14 does not show any change from the previous week, standing at 182 with an average price of \$2.20.

The drop in production of soft coal due to the holiday season was quickly recovered, but the pick-up in buying expected by some producers was not forthcoming. Interest now centers in the stock report to be made public about Feb. 1, which it is expected will show a considerable increase in consumers' reserves over Sept. 1, when they were about 56,000,000 net tons.

Conditions in the Middle West are quiet again fol-

lowing the few days of lower temperatures. Demand is easier and prices of some grades are lower. The reported move to cut wages in some Pocahontas mines provoked some discussion, considerable non-union coal from Kentucky and other fields meantime making its appearance in the Chicago market, quoted at low figures. Retail business in St. Louis is the one bright spot, with greater demand reflected in middle grade coals.

More Vigor in Ohio Market; Prices Steadier

There is more vigor in the Ohio markets than for some time and prices are steadier. Domestic coals improved slightly and while new orders have been freely placed some cancellations also have taken place. The steam-coal market was not stimulated and is quiet.

One market in which the cold wave did not affect the domestic trade to any great extent was at Pittsburgh. No distinct improvement was noticed, due principally to the well-filled cellar bins of both house owners and dealers. Industrial consumption is heavy and steel operations are reported as better than during December. There is no stimulus to buying in New England and industries are well supplied. Quotations for the better grades show a slight improvement. Further curtailment in industrial lines is under way.

The situation along the Atlantic seaboard is quiet. Some small contracts have been reported, while cement manufacturers are said to be picking up considerable slack. An improvement is noted in the export situation at Baltimore. Dumpings are on the increase when compared with the corresponding period of last year.

Production of soft coal during the week ended Jan. 5 is estimated by the Geological Survey at 9,031,000 net tons, an increase of 2,318,000 tons over the previous week. During the same period 1,419,000 net tons of anthracite was produced, an increase of 183,000 tons when compared with the week ended Dec. 29.

Midwest Flurry Calms Down

The considerable rush for Midwestern coal which followed immediately upon the opening of the below-zero weather of two weeks ago quieted down noticeably with the rise in temperature a week ago. Although most Illinois and Indiana mines worked an average of a little better than three days a week, few operations ran every day. Steam sizes from those fields softened a little, although the call for domestic coal was not sufficient to clean out all the "no bills" in the large sizes. Production did not get high enough to depress screenings much. Along toward the end of the past week there were signs of temporary car shortage here and there. This, however, was not serious.

Smokeless coals from the non-union East continued in Chicago at a mine price of \$2@2.25 without the increase which was expected if the bitter cold continued a few more days. A temporary shutdown of many Pocahontas operations growing out of a move to cut miners' wages was much discussed in the smokeless markets of the West, but the prices did not stiffen much, and by the end of the week no

shutdown had been made. A good deal of cheap non-union coal from various Kentucky and other Eastern fields continued to appear on the Midwest market, holding trade that Illinois producers lost by their policy of winter price cuts after they had stocked dealers during the autumn. This has taken about all the buoyancy out of a market that might have been made snappier by recent winter weather.

St. Louis Still Busy

St. Louis business continues good with the retailers. They did not clean up all their stock during the cold wave at New Year's but they got low enough to arouse them into buying. There has been a little demand for high-grade, but the greater call has been for middle-grade coal. Standard found a ready market with the domestic consumer. The 25c. advance in Standard did not stick, however. A burst of production set them back.

Country business has been unusually good, but for cheaper coals only. Wagonload steam continues to show improvement, while carload steam has eased up and there is a volume of screenings and nut unbilled, whereas a few

* Net tons, f.o.b. mines. † Advances over previous week shown in heavy type, declines in italics.

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913, 1918," published by the Geological Survey and the War Industries Board.

days ago those sizes were much in demand. This applies to the Standard and Mt. Olive fields. Generally speaking, conditions are considered good now, but it is temporary on account of the weather.

Kentucky Business Is Fair

Domestic demand in Louisville and throughout most of Kentucky continues fair following the cold wave, which was the most severe that Kentucky has felt since 1918. However, dealers are not buying greedily from the mines, for previous stocks are not all cleaned up. Some dealers are willing to sell at low prices rather than take a loss on degradation of long-held piles in their yards. But even at that, lump coal at \$7@-\$8.50 seems high to the public and there are reports of an increase in the use of gas and oil.

Conditions at the mines show little change of note. There is about 15c. to 25c. a ton spread between eastern and western Kentucky on most sizes, the eastern being the higher, but gas coal and non-gas are selling on a parity.

Northwest Slumps Again

The fearful burst of trade that started with the severe weather of two weeks ago resulted in two things: The docks could not fill the immediate orders fast enough and

shippers from everywhere began rushing thousands of cars of coal into the Northwest region, thinking that there was bound to be a good market for it. The market was good for a few days, owing to the congestion of business, but it slumped at once with the arrival of mild days and now the territory is full of all sorts of coal.

Shipments off the docks were heavy for awhile and the general upturn brought more public utilities and commercial building owners into the market. However, there was little or no change in the market quotations around the Head-of-the-Lakes except that Hocking screenings spread a flat \$3.50 price to \$3.50@-\$3.75. Some anthracite has been moving from Duluth to Winnipeg, especially egg, which is often slow and frequently is held over at the end of the season. Around Milwaukee the market during the week was fairly active.

West Runs Strong

Three weeks of winter have brought joy to all those of the Southwest who depend on coal for a living. In three days mine tracks were cleared of "no-bills." Two hundred and fifty cars were in distress in Kansas one Saturday night. By Tuesday noon every one had been sold and dealers, who had disregarded warnings from operators and jobbers that just such a situation might develop, were crying for more. For the first time this season mines are working full time through Kansas, Missouri and Oklahoma. Those in Arkansas that are open also are running full time.

In Colorado the pick-up has been a little less lively, but lost time due to "no market" has been reduced to about 30 per cent. The cold snap in Salt Lake City and other sections of Utah has stimulated business. Working time has jumped from less than three days a week to around four and a half days. Circulars are firmer all around. Few "no bills" are accumulating now.

Better Demand for Domestic Coals

There was a slightly improved demand for domestic coals in the Ohio markets following the cold wave the first week of the year, but it did not last. Additional orders were placed and some of these were cancelled when milder weather made its appearance. Steam business was not stimulated and with the large reserves on hand users are not inclined to make any additions to their stocks. Railroad buying is on the increase, as some are buying to guard against a suspension on April 1. Screenings fell slightly in price as a result of a better production of lump. Production of the mines reporting to the Southern Ohio Coal Exchange during the week ended Dec. 29 was 91,952 tons from 447 mines having a full-time capacity of 569,250 tons. Of the deficiency "no market" was responsible for a loss of 440,789 tons.

More vigor was injected into the Cincinnati market by the cold snap, and concessions on sales have been practically cut off. Domestic coals are moving well, while the call for slack has been falling off. The smokeless coals have improved their position. While the quotations for the general market of coals range from \$2.25 to \$3.50 for lump and \$1.25 to \$2.50 for mine-run quotations on what have lately become known as exceptional coals, such as Yellow Jacket, Southern Gem, Millers' Creek and some of the high free burning gas coals of West Virginia have ranged from \$3.75 to \$4 for lump and around \$2 on mine-run. The cold weather drained retailers' stocks at Cleveland, causing them to enter the buyers' market, improving conditions slightly. Steam-coal consumers are buying as they need the coal and there is little additional storing done.

The three-day cold snap did not affect the Pittsburgh market to any great extent. Demand for domestic coals did not improve, but industrial consumption remains heavy. Steel operations are improving and running fairly well, adding to the consumption of coal. Retail dealers have good-sized stocks on hand, while cellar bins are well filled. A slight improvement was noticed in the central Pennsylvania field the first week of the year; the number of idle mines is given as 365. The situation at Buffalo shows no material change. Slack is the strongest of all sizes.

Few Developments in New England Market

Aside from slight indications of firmer prices in some directions there are few developments of any consequence in New England. There has been no appreciable stimulus to buying; the somewhat enhanced prices for spot shipment are due rather to a much restricted supply available, not alone at the loading piers but at the various rehandling points as well. The industries are well supplied and we hear of no railroads or power plants that are likely to enter the market during January for any comprehensive tonnage; on the contrary there are decided letdowns in anticipated consumption, due partly to less business and partly to the mild weather. Many of the streams are running full, unimpeded by ice, and in general there are few points open to the energetic sales agent keenly anxious to place coal.

At Hampton Roads the amount of coal on wheels is relatively small, and while sales are only scattering, the average net return is rather better than a week ago. An Italian contract covered some weeks ago was the means of keeping one group of Pocahontas operations at work for enough time to tide over the period of maximum dullness, and now with the assistance of contracts on many of which during the fall delivery was deferred the agencies are able to pinch along with an occasional sale at \$4.75@4.90 per gross ton f.o.b. vessel.

Navy standard coals are being held at better prices also by factors at this end. Not much is being moved at the figures asked, but on the other hand the coal is in comfortable storage and there is practically no distress supply that it is incumbent upon anybody to dispose of within a limited time. To that extent the market is in better position.

There is no change all-rail. A few shippers of the quality grades profess to hear tidings of better results, but as yet there is no perceptible reaction in this territory. There are those who are even beginning to propose contracts for the coming year, but for the present they are likely to meet with a cool reception. Talk of a possible strike seems to rouse no interest whatever among buyers in New England; they recall that in 1922 the non-union fields were for a long period able to care for current needs, and besides, the price of coal is not the large factor in production costs it once was and only in a few lines is there much disposition to purchase supplies far in advance of probable use. It has been a season notable for spontaneous combustion, and not only was coal that was taken on early a poor purchase but there were heavy expenses resulting from unusually large reserves. This will all have a bearing on the inclination of the buyer as he faces the next coal year.

Seaboard Market Quiet

There is very little activity in the spot soft-coal market along the Atlantic seaboard. Contract coals move well, however, and prices are sustained. A little contracting is reported and some operators report that December's business was as strong as that of last January. Increased inquiries are reported by some shippers, while some assert that the output of their mines is sold up for the present month. Cars at the New York terminals ranged from 1,812 to 2,105 during the first five days of last week.

There was no improvement in the soft-coal market at Philadelphia last week. There is a fair demand and some

contracting has been reported. Consumers are not anxious to enter into a contract agreement. While there is no boom in evidence, manufacturers show signs of becoming more active. No note of encouragement is evident at Baltimore. Demand for both steam and gas coals is poor. A firmer market is predicted during the next few weeks. Comparatively little change was noticed in the West Virginia markets, due to the change in weather conditions. A little spurt affected the domestic market at Birmingham and the cold weather occasioned many new orders for domestic coals, which aroused the spot market.

Anthracite Situation Easier

Unseasonable weather with fair shipments of hard coal resulted in an easier market for domestic sizes at New York and also lower quotations for independent coals. Retail dealers hesitate before buying premium coals and will do so only when it is absolutely necessary. Stove and chestnut are the most wanted sizes. At both New York and Philadelphia small orders comprise most of the new business. Consumers are well supplied. Pea coal is moving well in the Philadelphia territory and dealers have made inroads into their stockpiles. Retail dealers at Baltimore had a sudden rush of orders early last week, and while shipments have not been heavy, there is a fair supply in most yards.

Production of beehive coke in the week ended Jan. 5 was 234,000 net tons as compared with 223,000 tons the previous week.

Coal-Mine Development in West Virginia

Fifty new mine plants were put in operation in West Virginia during the fiscal year ended June 30, 1922, according to the annual report of the State Department of Mines. In the same period 43 new power plants were constructed and 81 fans.

One of the most important equipment improvements made, indicating at the same time the growth of the industry, was the purchase of 8,235 mine cars, the Logan field leading with 1,329, the McDowell mines coming second with 1,144 cars, followed by Fayette mines with 1,113 and Raleigh mines with 1,070. In all 85 new tipples were built, Logan having 9 of such structures to its credit, Raleigh 8, Fayette 7, Greenbrier 7 and Monongalia 7.

Companies operating in the state built 828 new houses for miners, Wyoming mines building the largest number, 114. Another important addition to equipment was locomotives. There were 187 new locomotives put in use, Logan mines obtaining the largest number, 35. McDowell and Raleigh county mines purchased 23 and 24 locomotives, respectively. There were 124 new mine openings; Preston County led in such development, with the opening of 18 new mines, McDowell County ranking next with 11 new openings.

Foreign Market And Export News

Holidays Curtail British Coal Output; Coal Plentiful, Market Strong

Production of coal in Great Britain during 1923 was 278,501,000 tons, the highest recorded except for 1913, according to Board of Trade statistics. In the latter year the output was 287,412,000 tons, while last year it amounted to 251,850,000 tons. Output during the last week of 1923 was curtailed by the holiday season and amounted to 3,353,000 tons as compared with 5,886,000 tons the previous week, and 5,956,000 tons the week ended Dec. 15, according to a cable to *Coal Age*.

The labor situation is causing some uneasiness and loadings are slower due to the refusal of the tippers to work under the three-shift system, according to newspaper dispatches. Coal is plentiful, however, and the market remains strong.

The Welsh steam coal market continues in a strong position. There is a shortage of business and deliveries are somewhat behind, but orders on the books indicate that most of the mines will be heavily engaged well into January.

Inquiry from Europe is active, while business with Italy, South America and some of the Eastern countries is increasing. Belgium is inquiring strongly for coking coal.

The Newcastle market is also quiet. Nearly all kinds of coal are in good demand, best steams have improved slightly and there is a strong demand for gas coals.

Welsh Collieries Merge

A merger involving four large collieries near Swansea has been affected according to reports received by the Department of Commerce at Washington from Consul A. B. Cook, of the State Department stationed at Swansea. The collieries involved are the Great Mountain Collieries, the Ammanford Collieries, the Pontyberem Collieries, and the New Dynant Collieries. The new concern will be known as The United Anthracite Collieries, Limited, with a nominal capital of £2,500,000, of which £1,600,000 will, it is stated, be

offered to the public in the near future. The collieries involved are all important Welsh collieries, the oldest having been registered in 1891 and the newest in 1914. They employ at present about 3,000 workmen, and the annual total output of anthracite coal is about 500,000 tons.

This is the second important combine effected in the Welsh anthracite colliery field within the past six months, and the third important merger in the whole Welsh colliery field.

The new combine is further evidence of the marked inclination of Welsh industries to form into combines.

Less Coal at Hampton Roads

The coal market at Hampton Roads tightened noticeably last week, largely because of reduced supplies which was thought attributable to the reluctance of operators to resume full-time work after the holidays. Inquiries had not increased, however, and demand was only slightly improved.

Movement coastwise was slightly better, though retarded to some extent by recent storms. Bunker business was dull. Some foreign movements were noted, although not on the increase.

The tone of the market was firm, though higher prices were regarded as temporary. Shippers were exerting considerably more energy in booking cargoes, and increase in shipments was predicted on all hands.

French Industry Dull

Dullness continues in the French coal market, with supplies sufficient to meet the demand. Industry is quiet in all branches. Due to the excessive cost of British coal there is more buying of French coals. Mild weather affects the demand for house coals, and as money is scarce the "coalman" is only called upon when absolutely necessary. Retail yards are well stocked and dealers are not anxious to replace the small quantities of coal they sell.

The Belgian coal market is quiet, prices are easier and offers are made

to French buyers under the official tariff quotations, which would ordinarily attract buyers, were market conditions more satisfactory. French coal exports to Belgium during November amounted to 101,000 tons, while Belgian exports to France were 133,733 tons.

During November imports of coal to France amounted to 2,300,154 tons as compared with 1,935,821 tons in October. Coke imported was 431,592 tons as compared with 282,805 tons in the previous month. France exported 206,277 tons of coal in November as compared with 121,915 tons in October and 65,048 tons of coke as against 44,082 tons in October.

Traffic News

Hearing on Rate Increase

A hearing will be held by the Coal and Coke Committee, Trunk Line territory, in New York City on Jan. 24 on the carrier's proposal to advance rates on pea and smaller sizes of anthracite from mines on the D., L. & W. R.R. and D. & H. R.R. to Donnacona, Que. The proposed rates are \$5.65 for pea coal; \$5.28 for buckwheat No. 1 and \$4.52 for buckwheat No. 2 and smaller sizes, the increases amounting to 6c. on pea coal; 4c. on buckwheat No. 1 and 6c. on buckwheat No. 2 and smaller coals.

Coal Hearings Assigned

Hearings in coal cases have been assigned as follows to the Interstate Commerce Commission: Oklahoma City, Feb. 4, Superior Coal Co. vs. Pittsburgh & West Virginia; Omaha, March 10, Intermont Coal & Iron Corporation vs. Southern Ry.; Washington, March 11, Hood Coal Co. vs. Monongahela Valley Traction Co.; Denver, March 14, Victor American Fuel Co. vs. Denver & Salt Lake.

Calls Rates Unreasonable

Rates applied on coal between Murphysboro, Ill., and Mitchel, S. D., are unreasonable, in the opinion of Examiner Flynn, of the Interstate Commerce Commission. The case was brought by the Consolidated Coal Co., of St. Louis.

No Unjust Discrimination

The failure of the Chesapeake & Ohio Ry. Co. and the Virginia Ry. to make arrangements whereby mines of the Winding Gulf Colliery Co. would be enabled to avail themselves of the services, facilities and rates of either does not subject the coal company to unjust discrimination, in the opinion of Warren H. Wagner, an Interstate Commerce Commission examiner.

The Winding Gulf Co. points out that the railroads refuse to accord its mines the same treatment as is accorded other mines on the Kanawha, Glen Jean & Eastern. The defendants were asked to interchange at Pemberton and to afford facilities equal to those afforded the other mines. The examiner reaches the conclusion, in a report to the commission, that a railroad must be allowed some latitude for the exercise of business judgment and discretion in such a situation. A similar finding was made in the case of the Ragland Coal Co. in its case against the Virginian Ry.

Mines Supply 60 per Cent of Freight Moved

The mining industry contributed more than 60 per cent of all freight moved by railroads of the country during the third quarter of 1923, according to figures just compiled by the Interstate Commerce Commission, which show that all shipments offered aggregated 347,323,119 tons in the quarter review. Of that total, 205,254,449 tons were products of mines.

While the increase in all tonnage over the third quarter of 1922 was 29 per cent, the products of mines tendered in the third quarter of 1923 was 47.84 per cent greater than the movement in the corresponding quarter of the year preceding.

The Eastern district, by contributing 93,568,493 tons, tendered more mineral shipments to the railroads than any other subdivision of the country. The Western district was next with 68,599,074 tons. The South originated 23,180,655 tons, while the Pocahontas district contributed 19,906,227 tons.

Heavy Coal Traffic on N. & W.

The Norfolk & Western Ry. handled over its lines during 1923 30,662,850 tons of coal from the four districts it serves in southern West Virginia and Virginia. According to the records of the road the Pocahontas field produced 15,911,200, or more than half the total, Tug River district 4,399,850 tons, Kenova-Thacker district 8,683,400 tons and Clinch Valley district 1,668,400 tons. According to the records of the Pocahontas Operators Association the output in that field last year amounted to 15,397,038 net tons, as compared with 16,130,974 tons in 1922, 13,043,942 net tons in 1921 and 15,421,288 tons in 1920.

Publications Received

Change Houses in the Lake Superior Region, by Cleve E. Kindall. Bureau of Mines, Washington, D. C. Pp. 31; 6x9 in.; illustrated. Plans and description of a model change house in the Lake Superior region; many of the suggestions, however, can be applied to a change house in any locality.

Proceedings of The Rocky Mountain Coal Mining Institute, held at Salt Lake City, Utah, Aug. 27-29, 1923. Pp. 31, 6x9 in.; illustrated.

Report of the State Tax Commission, New York, 1922. Pp. 530; 6x9 in.; tables.

Report Department of Mines, Kentucky, 1922, Part I, by L. Blenkinsopp, chief inspector of Mines. Pp. 337; 6x9 in.; illustrated.

Report of Department of Mines, West Virginia, for fiscal year ending June 30, 1922; in two sections; by R. M. Lambie, chief of Department of Mines. Pp. 388; 6x9 in.; tables.

Efficiencies in Use of Bituminous Coking Coal as Water-Gas Generator Fuel, by W. W. Odell, Bureau of Mines, Washington, D. C. Technical paper 274. Gives re-

sults of an investigation relating to the manufacture of water gas conducted by the Bureau of Mines, Illinois State Geological Survey Division, and the Engineering Experiment Station of the University of Illinois.

Association Activities

The West Kentucky Coal Bureau Louisville, composed of operators from the two Western Kentucky operators associations, as well as independents, elected these officers at the annual meeting in Louisville on Jan. 8: President, Percy D. Berry, president of the Providence Coal Co., Providence, Ky.; Vice-President, James D. Overall, Reinecke Coal Mining Co., Madisonville; Secretary, C. E. Reed, Louisville; Executive Committee: Chairman F. P. Wright, president of the Crescent Coal Co., Bevier; F. D. Rash, president of the St. Bernard Mining Co., Earlington; Brent Hart, president of the Hart Coal Corporation, Morton's Gap; H. L. Tucker, president of the Rockport Coal Mining Co., Central City; M. B. Lanier, president of the Norton Coal Mining Co., Nortonville, Ky., and Birmingham, Ala.; A. W. Duncan, secretary of the W. G. Duncan Coal Co., Greenville, and C. F. Richardson, president of the West Kentucky Coal Co., Sturgis, Ky. Mr. Richardson was president of the association during the year just closed.

Obituary

George S. Baldwin, 88 years old, of Kenosha, Wis., died at his winter home at Pasadena, Calif., on Jan. 2. He founded the Baldwin Coal Co., which he directed for many years.

William K. Herzog, U. S. Consul at Vitau, Saxony, under Presidents McKinley and Roosevelt, died recently at his home in St. Louis after an illness of five weeks. For the past few years he was a special representative in St. Louis of the West Virginia Coal Co. Born in Basle, Switzerland, educated at Heidelberg and serving the United States for many years in consular work, he was well known to the local trade and was 59 years old. Besides a widow he leaves a grown son and daughter.

Michael W. O'Boyle, coal operator, of West Pittston, Pa., died at Miami, Fla., Jan. 9. He was born in Scranton, Pa., 70 years ago. He organized, with his two sons, the Pittston Coal Mining Co., disposing of his holding in the Alphine Milling Co. to devote his attention to mining interests. He had been a director of the Miners' Savings Bank, Pittston, and of the Citizens Electric Illuminating Co., of the same city.

Joseph Ruchaber, 47, for many years a coal operator in the Rich Hill district in Missouri, was found dead of heart failure recently in his apartments at Rich Hill.

Samuel L. Moore, aged 50 years, a member of the Moore Brothers Coal Co., operating mines at Emeigh, and who was a resident of Emeigh died in the Spangler hospital on Jan. 9 from injuries he received while driving mine cars from the mines. Recently the Moore mines have been working only on part time and the members of the firm were doing some of the outside work. Mr. Moore was born in Hollidaysburg in 1874 and had been connected with the mining industry for many years.

Coming Meetings

Northeast Kentucky Coal Association. Annual meeting Jan. 24, 1924, Ashland, Ky. Secretary, C. J. Neekamp, Ashland, Ky.

Rocky Mountain Coal Mining Institute. Winter meeting, Feb. 13-15, Albany Hotel, Denver, Colo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

New England Coal Dealers' Association. Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

Canadian Institute of Mining and Metallurgy. Annual meeting March 5-7, King Edward Hotel, Toronto, Ontario, Canada. Secretary, G. C. Mackenzie, Drummond Building, Montreal, Quebec, Canada.

News Items From Field and Trade

ALABAMA

The State Board of Mine Examiners will hold a session in the offices of Chief Mine Inspector C. H. Nesbitt, Lincoln Life Building, Birmingham, Jan. 21 to 24, to examine applicants for positions of mine foreman, first and second class, and fireboss on qualifications necessary to fill such positions in coal mines of the state.

George B. McCormack, prominent coal operator, has instituted suit in the Chancery Court of Walker County, at Jasper, to recover an alleged half interest in the site on which is located the Gorgas steam plant, in which the government recently sold its interest to the Alabama Power Co., the latter having installed and owned the initial units. Mr. McCormack claims that his interest in the power plant site has never been acquired by the power company.

The Pratt Warrior Coal Co. of Jasper has twenty-five new homes under construction at its Ivey Bluff mines on the Warrior River in the southern part of Walker County. The Pratt Warrior recently leased the Ivey Bluff mines to the Gulf States Portland Cement Co., of Demopolis, which has increased the output of the mines to 300 tons of coal daily. With the addition of this housing of more miners, another substantial increase in production will be made. The cement company has installed motor haulage at these mines. Ivey Bluff mines are located near the banks of the Warrior River, several miles from a railroad and all coal is transported down the river in barges.

The U. S. Supreme Court in a decision handed down Jan. 7, refused to order the Court of Claims to assume jurisdiction in a suit against the government by the Corona Coal Co. to collect \$107,431 alleged to be due on a railroad contract while the lines were under federal control, the difference accruing between a rate of \$1.96½ a ton under the contract and \$2.40 per ton fixed by the Government Fuel Administration.

ARKANSAS

The Bernice Coal Co.'s mine at Russellville, has resumed work after having been idle since the tippie was burned October 16. A temporary tippie was erected. A full force of about 400 men works this mine.

COLORADO

The La Veta Coal Co. has been incorporated in Alamosa, with a capital of \$100,000, by P. Fern, A. H. Samuels and L. Jordan.

ILLINOIS

E. L. Stanton, for the past six years sales manager for the Lumaghi Coal Co., of St. Louis, severed his relations with that company Jan. 1, and is succeeded by C. V. Beck, who has been advertising and promotion manager for the Lumaghi Coal Co.

The Taylor Coal Co. of Chicago, has changed its name to the Franklin County Coal Co. during the process of absorbing the Bickett Coal & Coke Co.'s holdings and the consolidation of the Old Taylor properties with those of the Bickett interests. Herbert H. Taylor continues as president of the new concern and C. A. Bickett, after long years as a prominent figure in the Illinois coal industry, retires. Issue of \$2,750,000 first mortgage 7 per cent serial gold bonds of the new company is being offered for sale. The bonds mature \$137,500 annually from Jan. 1, 1925, to 1944, inclusive.

The tippie of the Centralia Coal Co. burned at Mine No. 5 recently at an estimated loss of \$100,000. The mine employed 850 men.

The No. 1 mine of the Bell & Zoller Coal Co., at Zeigler, broke its hoisting record this month by hoisting 7,700 tons in eight hours. This is the mine that ran the famous production race with Orient No. 1 two years ago, winning for the month's output but losing the one-day record which stands at 8,210 tons. Zeigler No. 2 mine has a record standing at 6,699 tons. The total tonnages of these two mines for the year

of 1923 is over 2,000,000 tons, which is rated as the highest tonnage in the world for any two mines. The output for the mines during the year in railroad cars would reach over 300 miles, or if the caboose of such a train was in Zeigler, the engine would be passing through Chicago.

The Chicago Wholesale Coal Shippers' Association on Jan. 9 in annual meeting elected these officers: President, P. H. Holland; vice-president, Roscoe B. Starek; treasurer, T. A. Brahm; secretary, George H. Merryweather; directors, Charles L. Derling, James Anderson, Tom C. Irwin, N. L. Walton, J. H. Weil and W. C. Hill, who is the retiring president.

INDIANA

F. D. Roberts, who has been serving as traffic manager of the Indiana Coal Merchants' Service Bureau, an organization composed of a large number of retail coal merchants of the state, has been appointed manager of the bureau, to succeed R. R. Yeagley, who has resigned.

KANSAS

A consolidation of the Midland Coal Co. and the Jackson-Walker Coal & Mining Co. has been effected by H. G. Kellogg, C. H. Markham and C. P. A. Clough, at Kansas City, Mo. The Midland Coal Co. will hereafter handle the affairs of both concerns. Operating principally in Kansas.

KENTUCKY

Estimates of 1923 coal production in Kentucky show an anticipated output of 36,000,000 tons, as against 42,000,000 in 1922, the peak year, and 38,000,000 in 1920. In 1922 with the national coal strike in effect, Kentucky operated full time, with a large car supply and did a great business. A loss of five to six millions tons over 1922 is predicted, which is quite good in view of steady over production in all fields, and keen competition for business at giveaway prices in the autumn.

Coal interests of Kentucky are all set for the bitterest legislative fight on record, the legislature having convened Jan. 8 after a lay-off since 1922. There has been stiff support for a coal-tonnage tax, which has the backing of the agricultural and land-owning interests. Such bills have been defeated in the past. At the last session a sum was appropriated for a study of the coal-taxing problem, prior to action, this giving the coal interests two years' grace, which, however, has not helped the cause any.

The Elkhorn Collieries Co., Trenton, Ky.; Dudley Coal Co., Backey; Marion Coal Co., Rockhouse; Ajax Coal Co., Lotts Creek; and Himyar Coal Co., at Domino, are planning to resume operations after being down for some time.

Below zero weather on Jan. 5 prevented continued rise of the Ohio after it was about 4 ft. above the danger line, and probably saved business interests of Kentucky, including river coal companies, a good deal of money.

The Little Pond Coal Corp. has been formed and will develop property at McAndrews. H. G. Happersett, the treasurer and construction engineer, is located at Route 3, Ronaoke, Va.

Don D. Walker, for some years in charge of the Jeffersonville and New Albany (Ind.) divisions of the St. Bernard Mining Co., has taken charge at Louisville as well, and will now look after business of the three cities. W. B. Gathright resigned on Jan. 1 as manager of the Louisville office.

Notice has been filed of the dissolution of the Paint Cliff Mines Co., Louisville, claimants being asked to present all claims to Treasurer J. H. Schneider, 715 Inter Southern Building, Louisville, within sixty days.

The Reliance Coal & Coke Co., of Glomawr, is reported to have purchased the Defiance Coal Co., of Defiance, on Carr's Fork.

MISSOURI

Citizens of Moberly are making an effort to revive the old Busy Bee mine, in that city, which has been closed because of an unpaid payroll. More than 150 merchants and others attended a meeting at Moberly and steps were taken to continue operation by some form of public aid to the operating company.

David and John S. Lodwick, of Mystic, Ia., who recently purchased the Mosby mine at Mosby are making extensive improvements on the plant. They have installed much new machinery and have rebuilt the entire plant since purchasing it from the former owners. The mine is now turning out 100 tons of coal a day. This will be increased to 150 tons a day as soon as the plant is under full headway.

NEW YORK

The New York Stock Exchange on Jan. 10 admitted to trading on a "when issued" basis the 1,400,000 shares of capital stock of the Reading Coal & Iron Corporation without par value. Certificates of interest of the same company also were listed. The Exchange's Committee of Securities has ruled that inasmuch as due bills on Reading rights can no longer be transferred with stock certificates, all deliveries, beginning Jan. 10, must be accompanied by due bills for said rights until the respective stocks sell ex rights.

Judge Learned Hand, in the U. S. District Court at New York on Jan. 8 signed an order in the dissolution suit instituted by the government against the Lehigh Valley Railroad Co., appointing four trustees to exercise certain rights specified in the dissolution decree in relation to the capital stock of the Lehigh Valley Coal Co. and Cox Brothers & Co., Inc. The trustees for the Lehigh Valley Coal Co. are William Potter and the Girard Trust Co., of Philadelphia; the trustees for Cox Brothers, Inc., are Thomas R. Marshall of Columbia, Ind., and James Neale, Jr., of Minersville, Pa. The order provides that if there should come any disagreement among the members of the groups in the exercise of the duties imposed upon them as trustees, application for advice shall be made to the court.

Arthur Hamilton and Harry W. Maynard, of the Central Railroad of New Jersey, were elected directors of the Coal & Iron National Bank, of the City of New York, at a meeting of stockholders Jan. 8, 1924.

The Davis Coal & Coke Co. has opened an office in the Singer Building, New York City, with H. C. Pridham as manager and D. W. Bowden, sales agent. Mr. Pridham and Mr. Bowden formerly were connected with B. Nicoll & Co. and are well known to the coal trade.

P. A. Paddock, formerly of Dexter and Carpenter, Inc., is president of the Paddock-Walther Coal Corporation, which has just opened offices in New York City. W. M. Walther is secretary-treasurer of the corporation. Others connected with the new concern are A. Themans, C. G. Appleton and George M. Carpenter, Jr., all formerly associated with Dexter & Carpenter. Mr. Themans will look after the anthracite and domestic bituminous-coal trade. Mr. Appleton after the tidewater, coastwise and transportation business, while Mr. Carpenter will have charge of the Cincinnati (Ohio) office, he having occupied a similar position with the old Dexter & Carpenter firm.

NEW JERSEY

Governor Silzer, in his annual message to the State Legislature, told the members of that body that the anthracite problem must have earnest attention and that some relief must be obtained for the consumer. He advised the following: "Enactment of a statute which would protect the consumers of this state against all unlawful practices and profiteering after the coal gets within the state; an appeal by the state to prevent extortionate and unlawful practices while the coal is in interstate commerce; an appeal to the Governor and Legislature of Pennsylvania for a statute regulating the industry there and for relief from the agencies which raise the price and limit the output."

A bill introduced in the New Jersey State Senate by Senator Woodruff of Camden, provides that 2,240 lb. shall be the legal weight for a ton of anthracite. Assemblyman Powell, of Burlington, has introduced in the House a concurrent resolution which would request Congress at once to direct an investigation of the anthracite industry.

NORTH DAKOTA

The Saskatchewan Government has contributed to the plant of the Dakota Lignite Products Co., at Minot, a gas washer, condenser and exhaust system and fire brick tile for oven use. The Canadian Government is interested in the development of the plant and seeks to aid it in this manner.

OKLAHOMA

Operators in the Henryetta field of Oklahoma having mines on the Frisco R.R. are aroused over that company's determination to enforce ruling No. 9 of the Oklahoma Corporation Commission, governing car distribution. The operators declare that such action, if enforced, will mean the cutting down of the mines' running time, thus causing hardships to hundreds of miners and resulting in the shutdown of several mines. Under the old ruling if a mine's capacity was ten cars a day, for example, and half of this could be loaded as "no bills," the mine could still get its full quota of cars for the next day. Under the new ruling the railroad will charge the "no bills" cars against the quota of cars for the next day.

The Henryetta Coal Mining Co. of Henryetta, established in 1906 and one of the oldest in the Henryetta field, has been forced to abandon its shaft, due to a squeeze.

PENNSYLVANIA

C. E. Leshar has been appointed assistant to the president of the Pittsburgh Coal Co., Pittsburgh. The appointment became effective Jan. 1 and Mr. Leshar's headquarters will be in Pittsburgh, according to an announcement by W. K. Field, president of the company.

James B. Neale, largest independent operator in the Schuylkill field, has returned from Canada with the information that the Canadian Pacific R.R., which substituted the use of oil for anthracite in many departments, has returned to anthracite. Oil did not prove satisfactory and was not always to be had when wanted, he said.

Marcus A. Walker, who for the past eight years has been mechanical engineer for the Hudson Coal Co., has resigned, to accept a position as district manager of the Chance Coal Cleaner Co., with offices in Scranton.

The Jordan Coal Co., composed of a group of Scranton independents, is rushing work on its new colliery between Quakake and Delano. Three eight-hour shifts are employed in the erection of a breaker.

The State Supreme Court on Jan. 8 upheld the constitutionality of the state anthracite tax law in an appeal from the decision of the Dauphin County Court in the case of the Commonwealth vs. the Philadelphia & Reading Coal & Iron Co. and other appellants. It is not known whether there will be any attempt made to get the cases into the federal courts. The cases decided in the Supreme Court will involve the whole Reading, Lehigh & Navigation, Alliance and Cranberry groups. There are several others, but these cases will cover those producing the greatest amount of tax.

The annual banquet of the Coal Club of Philadelphia, will be held in the Bellevue-Stratford Hotel, Philadelphia, Jan. 31. Noah H. Swayne, president of the club, will act as toastmaster. The speakers will be Dr. J. T. Holdsworth, president of the Pennsylvania Joint Stock Land Bank; Ira Jewell Williams, of the Philadelphia Bar, and Charles L. Dering of Chicago, president of the American Wholesale Coal Association. The officers and executive committee of this latter association will be in Philadelphia for their quarterly meeting on Jan. 31 and will attend the banquet in a body. The banquet will be preceded by the annual election of officers.

According to an announcement made in Harrisburg on Jan. 7 by Secretary of Mines Joseph J. Walsh each of the fifty-two anthracite and bituminous mine inspectors in Pennsylvania may be given a month's leave of absence without pay. The action is necessary, press dispatches said, to conserve the department's fund, which would be inadequate were the force to continue on full time for the remainder of the biennium. As announced in Harrisburg Secretary Walsh will lay off the inspectors at the rate of several each month so as to not cripple the inspection work. Under the mine laws of Pennsylvania inspection in the anthracite regions must be made at

least once every thirty days. There is no specific number of inspections for the bituminous coal mines. By leaving off each inspector for one month, \$20,800 will be saved to the department.

Development of hard-coal operations in Quakake Valley, south and west of McAdoo, is being rushed at a rapid pace. The Panther Creek Valley company has opened workings on the mountainside and is employing three eight-hour shifts, as is the Candelmas Coal Co., of Wilkes-Barre, at Silver Brook.

During 1922 and 1923, according to a survey made by the State Geological Survey, approximately 200 new bituminous coal mines were opened in Pennsylvania, James D. Sisler, associate state geologist, has announced at Harrisburg. His report shows that the majority of the openings were in Allegheny, Cambria, Clarion, Clearfield, Fayette, Indiana, Jefferson, Somerset and Westmoreland counties. The report shows that about twenty-five mines in the Monongahela and Pittsburgh district have been reopened and pumped out for the purpose of removing pillars and working thin veins. Many of these mines have not been operated for thirty to fifty years and the increased value of the coal for coking and steam purposes is given as the reason for the reopenings. The Pittsburgh coking coal, the production of which is largely from mines in Westmoreland and Fayette counties, will be exhausted within a comparatively few years, it is said in the report, and the only large remaining area will be in Greene County. It is shown by the survey that the supply of Pittsburgh steam coal is about exhausted. Most of this is coming from the area about Allegheny County. The Morshannon bed, in Clearfield County, also is nearing exhaustion.

The State Department has approved the merger of the Springfield Coal Mining Co., the Bloomington Coal Co. and the Springfield Coal Co. into the Springfield Coal Mining Co. The new company has a capital stock of \$2,000,000 and George E. Metzger, St. Benedict, is the treasurer. The central office of the merged company is at Ebensburg.

Among the State charters issued are the following: Prospect Shaft Mining Co., Ramey, \$50,000 capital; purpose, mining, producing and selling coal and coke; incorporators, W. R. Minds, Ramey, treasurer; John H. Minds, Philadelphia, and George Minds, Ramey. Triangle Coal & Coke Co., Pittsburgh, \$25,000; mining and selling coal and coke; incorporators, William B. Atwood, Dormont; W. C. Maratte, Coraopolis, and George W. Kilpatrick, Pittsburgh. Raymond A. Siedel, of Philadelphia, is treasurer. Junction Coal & Coke Co., Pittsburgh, \$60,000; mining and selling coal and manufacturing coke; incorporators, D. L. Feick, Pittsburgh, treasurer; S. J. Minnick, Bruceton, and R. S. Porter, Broughton. Smutzinger Coal Co., Munson, \$50,000; mining coal and manufacturing coke; incorporators, Annie Smutzinger, Philipsburg, treasurer; Jacob Smutzinger, Philipsburg, and Fred Eisenhauer, Munson.

TEXAS

Dr. J. P. Spark and associates have purchased the mining plant and holdings of the Empire Fuel Products Corp., Inc., at Rockdale, and will operate them.

Charging that workmen's compensation insurance rates in Texas are unjust to lignite mine owners, five Texas coal companies have petitioned the State Insurance Commission to adjust the rates. The Texas operators contend that lignite rates in that state are based on conditions in Kansas, which they maintain, are far different from conditions in Texas. A hearing on the matter was held Dec. 10 at Austin.

UTAH

The U. S. Land office has auctioned a lease of 1,120 acres of land to the Union Coal Co. for a \$30 bonus. The minimum tonnage is to be 20,000 annually after the third year. Investment minimum is to be \$40,000. The royalty per ton is 10c.

WEST VIRGINIA

Frank Costanzo, of Warwood, president of the Wheeling Coal Co., announces that the Wheeling Coal Co. has purchased from the J. C. McKinley interests, of Wheeling, 1,000 acres of coal land near Warwood. The

company will increase its capital stock. Extensive construction work is already in progress and other improvements are contemplated.

Two large coal firms have been launched in Huntington by Captain R. R. Smith. The larger of the two companies—the Agee Coal Co. is capitalized at \$200,000. It will operate mines in the Logan County field, although its headquarters are to be in Huntington. The other company organized by the same people is to be known as the R. R. Smith Coal Co., capitalized at \$100,000. This company will act as a selling company only. Active in effecting the organization of the companies were R. R. Smith, W. P. Neekamp, G. I. Alexander, F. D. Clifford and E. H. Adams.

WISCONSIN

Milwaukee coal companies which operate docks on the upper limits of the Milwaukee River are somewhat disturbed over the fact that the city authorities evince a desire to close the river to large vessels by establishing fixed bridges across the channel in the interest of economy and uninterrupted street traffic. The Board of Harbor Commissioners will make a survey of the situation. In a matter of this nature the federal authorities have the final decision.

The Milwaukee-Western Fuel Co. will spend a large sum of money in improving what is known as Cherry Street dock on the Milwaukee River in Milwaukee. The dock will be straightened by the removal of a 10-ft. angular projection, thus allowing a 14-hold boat to unload without resorting to the use of scrapers to get the coal under the rigs. A new concrete dock will replace the present wooden structure.

WYOMING

The Employee's Magazine of the Union Pacific Coal Co. and the Washington Union Coal Co., published at Rock Springs, is a new publication for coal workers. This neat-looking 16-page paper, full of news and technical departments and illustrated with photographs and home-made cartoons, came into life with the January number. Mrs. Atlanta E. Hecker is the editor. The employees' magazine is the outgrowth of an idea of Eugene McAuliffe, new president of the companies.

CANADA

James B. McLachlan, deposed secretary of the United Mine Workers, District 26, has been denied a new trial by the Supreme Court, at Nova Scotia and may be required to serve the sentence of two years in Dorchester penitentiary, passed upon him following his conviction in October last on the charge of having published a seditious libel.

F. W. Gray, who has been associated with the British Empire Steel Corporation since its formation, and was previously with the Dominion Coal Co., has been appointed assistant to President Roy M. Wolvin.

A. J. T. Taylor, president of the Combustion Engineering Corporation, Ltd., Toronto, recently addressed the Engineering Institute of Canada and the Dominion fuel board, on "Powdered Coal as an Industrial Fuel." "This method of using fuel," said Mr. Taylor, "not only presents a means of improved results with the present available commercial fuels, but makes possible a still greater conservatism of those fuels by replacing them with many of the lower-grade local fuels that are at present unsuited for burning by ordinary means."

After years of experimenting in the production of peat at Alfred, Ont., the Dominion Government has interested private capital and a company has been formed in Montreal to take the plant over and operate it on a commercial basis. Three thousand tons of peat was produced last year and it is stated that peat can be produced at \$3.50 per ton. It cannot be shipped economically more than 100 miles. The total area of peat bogs in Canada is 27,000 square miles. Seven bogs within shipping distance of Toronto are capable of producing 26,500,000 tons.

A coking experiment with Nova Scotia and New Brunswick coal will be conducted at Hamilton, at the new coke ovens constructed by the local gas company, under the auspices of the Dominion Government on Jan. 21. The test will be made under the observation of Charles Stewart, Minister of Mines; Dr. Charles Cammell, Deputy Minister, and experts of the Mines Department.

Number 4

Rid Mines of Convict Labor

NO ONE who has employed prison help in coal mines is an enthusiast for that class of operative. Nowhere is the employee less under observation and control than in a coal mine, yet nowhere, every miner will admit, is discipline more needed for the safety of the individual himself and for the security of everyone else in the mine.

The job of coal miner is one calling for loyalty and willingness to labor. True some miners have neither quality but there is always a fair admixture in any aggregation of men. With prison labor, loyalty and industry are notably absent, though probably even in prison mines, they are not invariably lacking. Unfortunately, convicts usually come into their regrettable condition by reason of the fact that they have neither of those qualities and are at war with the rest of humanity. They often are as insufferable in their own homes as they are to their neighbors.

It is useless to call on the coal industry to rid itself of prison labor. The coal industry is not to blame. Only those who enter into such contracts and such states as permit it are responsible. The appeal must be to the public in states which harbor such institutions.

Mining is not so dangerous inherently as to make the employment of convicts a crime. It is at best an act of folly, but this it certainly is and for that reason it should be condemned.

Is This What Was Meant?

PUZZLING indeed is the attitude of certain inspectors in regard to the disaster in No. 1 mine of the Mount Jessup Coal Co. A big fall of rock occurred in that mine, due, it is said, to the presence of 30 ft. of loose sand in the roof. This loose sand is not uncommonly found in the northern anthracite field. Where it occurs, precautions should be taken against it.

We are not clear that the inspectors were in any way amiss in demanding that workings in coal likely to be covered by such treacherous overburden be provided with unusual safeguards. That they should be drilled and that the areas of sand and its depth should be determined is a reasonable suggestion followed by one company at least. That the inspectors should be informed as to its presence is not a startling proposal. Faults also may have to be taken into consideration as possible causes of sudden roof collapse.

However, so much granted, one cannot understand the advisability of compulsory testing of the roof by boreholes in areas where loose sands and gravels are never found or when found are covered with thicknesses of firm deposits amply adequate to protect the workings.

The greater part of the coal in the State of Pennsylvania, including practically the whole of the bituminous coal field, is free of glacial drift. Only in the first basin are faults found except a few unimportant ones near the coal crop. No safety is to be gained by drilling such measures. We can only assume that the inspectors in making their report referred to areas such as that on which they were reporting and not to the many areas where loose sands and gravels, true faults and extensive fractures are entirely unknown.

Keep Moving

CONTINUITY of operation is the test of machine loading. Many machines already on the market load ample tonnage per minute to satisfy the operators who buy them, but unfortunately they can be expected to maintain that tonnage through the day only when cars are delivered steadily through the whole course of the shift. The question, therefore, is one of transportation. Only one car ordinarily can be delivered in a room at a time.

With a good roof and some cribbing or heavy posting, a trip can be loaded at a longwall or a pillar face, but cribbing and heavy posting is expensive to maintain and remove and may be inadequate in the control of the roof, as it interferes with its prompt collapse and therefore with the relief of pressure consequent thereon. This consideration reduces the length of the trip, and with a short string of cars the efficiency of the machine loader is greatly reduced. A conveyor leading to the roadway is a solution, but with many rooms equipped with many conveyors, congestion in the heading is inevitable. A heading conveyor can be placed on the roadway, as is advocated by the author of the article "Modernize," printed in this issue. Such a conveyor will meet this difficulty.

If there is more than one heading delivering to a single main entry, however, and these headings are close by one another there will be congestion on the entry and more trouble. Another conveyor, one on the entry, is the solution. This conveyor may profitably be extended so as to eliminate the use of cars altogether, except for supplies. Consequently the author of the article, recognizing this fact, makes conveyors serve for the transportation of the coal from the face to the tipple. Who shall say that he is not justified?

The face must be cut and shot, however, and meanwhile the room is not working. By moving the machine loader and its men to another room this difficulty is met at least in part. The loaders and cutters do not have far to go, and only the room conveyor is idle while the face is cut and shot and while cutter and loading machine are maneuvered into place. A machine that cuts as it

loads would enable operations to be continuous, especially if the coal does not have to be shot down.

Large changes are coming. Mines will become smaller and the work in them more concentrated and the expenditure per acre under operation will be increased. At the same time the capital outlay per ton of daily output will be lowered.

Narcotism

STRIKES have restricted output, and car shortages have aided in preventing the shortage of coal from being immediately replenished. Thus prices which have fallen to abnormally low levels have been raised to levels abnormally high. Naturally, companies facing bankruptcy or a severe depletion of resources have not viewed strikes and car shortages with any great degree of regret. One cannot much wonder at that as they present another chance to correct an unfavorable balance. But nothing has done more to bring an excess of new mines than this same condition.

Among these new operations are many so inadequately equipped that they cannot face the pressure of competition when the shortage of coal ceases. The fly-by-nights, or snow-bird, mines promptly close down when the flurry in coal comes to an end.

All new mines, however, are not of this class. Others there are equipped up to the minute and well able to drive the older mines to the wall. Some of these old operations with all their new equipment are so inherently out of date as far as layout is concerned that they cannot be operated in competition with mines designed with all the advantages of modern engineering. Not only are their roadways and airways badly planned and impossible to improve but they are unduly long. The new mines have all the advantage, and the last state is worse than the first. After the flurry conditions are more unbearable than before the strike or car shortage.

In fact the strike is like an opiate. When the drug's effects are expended, nothing but a second shot of the hypodermic will ameliorate the patient's condition. Narcotism is not popular among medical men because it leaves the patient weaker than before the application. Neither is a strike to be advocated as a means of renewing the vigor of the coal industry. Safe and sane business is based on full-time operation, not on spasms of activity followed by months of quiescent slumber.

As the doctor fears the *sequelae* of a drug, so should the coal industry view with apprehension the prospect of becoming victim to the unfortunate evils which follow in the train of an activity artificially created. If anyone would judge the effect of such temporary stimulants, let him view the course of the copper and machinery industries since the war.

"PLEASE BOIL IT DOWN TO ONE PAGE," begs a Congressman of a coal operator who has a plan for remedying some of coal's ills. Not many Congressmen would take the trouble to ask even that. They are just about like the coal operator—whose name is legion—who does not read the Coal Commission's report; they simply will not dig through reams of verbiage to get people's ideas. The wastebasket and the dusty shelf are ever ready for long-winds. Tell your Congressman what, if anything, you think ought to be done about coal; but beware of verbosity and the wastebasket.

Passing of the Hand Shovel

REDUCTION in the number and character of immigrants is assured if the House Immigration Committee's quota bill is enacted into law. The number of immigrants, already reduced, will be further diminished by almost one-half, and the particular sources of labor that have replenished the coal fields will be decreased in even larger proportion, for the number of men of the type that enters the coal mines will be more largely decreased in all probability than the figures of the new and old quota would indicate.

The United States is determined that America shall continue America. The people of this Republic are determined that the country shall no longer be surfeited with unassimilated labor. The immigration quota being based on 1890 instead of 1910, a large percentage of northern Europeans will be admitted and a small percentage of southern Europeans. The former do not take any more kindly than Americans to arduous labor. Few miners will come here and those who do will be unable to understand why they should produce as large a tonnage as has been the custom of American miners. They thoroughly approve of European standards of production and forget that American conditions of seam and system justify larger tonnages.

Consequently we may before long cease to find the coal fields populated beyond the labor demand, as they have been too generally in the past. Incidentally it may be remarked that we shall find it difficult to open new fields. Old fields will draw on the present surplus and perhaps for a while obtain men from other industries surrounding the coal fields, but new regions will have recourse only to transported native labor and to the sparse populations already occupying the neighborhood of the new mines.

Some time back when the loader was still new and portable conveyors fed by hand labor seemed likely to hold for a while the mining field, a superintendent was asked what he thought of these new-fangled devices. He replied that he preferred the "Franz Josef shovel," meaning the hand shovel in the hands of the subjects of the Emperor Francis Joseph. Many were then arriving, and splendid workers most of them proved to be.

Today the "Franz Josef shovel" is decreasingly present. We have to find a substitute, and the mechanical loader promises to serve the purpose. It inevitably must come, for the modern laborer takes but unkindly to arduous toil. The power loader is the only way to meet the problem.

Many an operator does not want to have to employ any more men. They take too many houses. No longer are any single men available or men having wives and children in Europe. Bunk houses accordingly will no longer aid in filling the needs of the operator. Good homes must be built, and with rents what they are—and they do not promise to be increased—the building of houses is unprofitable. The stores no longer pay an exorbitant profit. So the cry is "More coal without more men" or "with less men," for the single men are becoming married or bringing over their families and demanding suitable housing.

For this reason the power loader is becoming essential, and the mines must be worked more and more by machines. The pressure is economic and it cannot fail to be met. Only loading by machine and by face and room conveyors will meet it.

Coal-Strip Enterprises Grow in Western Kentucky

Sunlight Mining Co., of Madisonville Led Field with First Plant Opened About Three Years Ago—Twelve Pits Now Running and Three More About to Open—Operators Face Many Problems

BY A. W. WILLIAMS
Louisville, Ky.

STRIP mining in western Kentucky has made such forward strides of recent years that it is much in the spotlight in the coal industry of that region. Although the first stripping operation is only three years old there are now no less than twelve strip pits operating, three more are actively preparing to run and other companies are interestedly scanning the field for a chance to get into the game. During the month of November a total of 1,800 cars of strip coal were moved out of the field. This represents at least 10 per cent of the production of the western Kentucky field and is therefore already an important factor.

"And the best thing of all that can be said about stripping," says a strip operator who has heard much comment from shaft-mining interests about the doubtful future of stripping, "is that out of 340 underground mines in western Kentucky, including potholes and all, during early December only 150 were active and most of these got only part time, whereas every stripper that is ready to run was running. Coal can be mined more cheaply by the strip method, and naturally strip mines were underselling deep mines."

Development of strip operations in the field during 1923 was especially rapid. It was so rapid, in fact, that prospective operating companies made mistakes. It is always easy to figure on paper that there is a given tonnage of coal underlying a certain acreage, that the cover is of a certain depth and that the cost of removing it will be exactly such and such; but strip-

ping often is fraught with many surprises and much heartbreak.

Companies hastily opening stripping land have found that the overburden was not uniform, that it was spotted with hard formations expensive to move, that the coal seam varied astonishingly in thickness and often turned out to be shot full of "rust" in spots that lowered the uniform quality of the deposit, that drainage became difficult and expensive when the coal didn't lie right, that breakdowns of the few big expensive machine units upon which the pit depended were vexing and expensive, all of which doubled or trebled the paper cost of stripping coal. And finally, market fluctuations upset the roseate preliminary calculations. Some western Kentucky operators struck all of these difficulties.

SPENT \$25,000 YET DID NOT BUY COAL LAND

Some mighty careful studies were made by certain of the prospective stripping companies before any machinery was bought. One concern is reported to have spent \$25,000 in a thorough drilling of every part of a 450-acre tract and then to have declined the lease. It was a costly venture in prospecting, but the cost was nothing compared to what might have been wasted had the first few drill cores been accepted as adequate basis for going ahead. It is an expensive thing to erect a tippie with all the coal-cleaning and sizing equipment necessary to prepare strip coal for the market, and then to buy and assemble a big steam shovel and spend a few months encountering the unforeseen.

The industry being new in western Kentucky, the development companies have a lot to learn. Kentucky's first important stripping plant was opened only about

Cleaning is one of the serious problems of the stripper. The headpiece shows the picking table of the Sunlight Mining Co., near Madisonville, Ky. No less than fourteen men are on duty at one time taking out the refuse. Washers also are employed at some of the properties.

RIPPING THE OVERBURDEN FROM WESTERN KENTUCKY COAL WITH A MAMMOTH SHOVEL

Most of the big shovels in the rapidly spreading stripping movement of that section of Kentucky are steam-operated. Central-station electric service is none too general yet. The cover on this coal varies at most strip plants between 25 and 35 ft., but in spots runs up as high as 50 ft. West Kentucky as a stripping field was only lately discovered.

three years ago by the Sunlight Mining Co., of Madisonville. The Western Collieries Co. and the Magic Collieries Co., at Ilesley, followed closely. Subsidiary organizations of underground mining companies began to appear along with outright stripper outfits. The number of them steadily increased through 1923. During November two new strip pits were opened by the Morrison Coal Co., and the Curshaw Coal Co., both of Centertown. It is reported Birmingham (Ala.), interests are behind the Morrison company.

Within the three years fifteen developments started, including three which have not yet produced coal. These companies are now in the active class: Sunlight Mining Co., of Madisonville; Western Collieries Co., with two plants at Ilesley and Crabtree; Magic Collieries Co., of Ilesley; Hawley McIsaacs Co., of Carbondale; D. B. Gore & Co., of Providence; Harris Coal Co., of Island; Kentucky Washed Coal Co., of Nonell; Midstate Coal Co., of Morton's Gap; Dempster Construction Co., of the same place; Morrison Coal Co., of Centertown, and Curshaw Coal Co., also of Centertown. Strip pits are now being started by the Hawley McIsaacs Co. (No. 2 mine) at Lewisport, by the Dawson Daylight Coal Co., at Dawson Springs, and by Boddie & Powell, of Earlington.

It is known that at least two strip operations are located on properties belonging to the St. Bernard Coal Mining Co., of Earlington, shaft-mine operators.

The new Dawson Daylight Coal Co. is controlled by K. U. Meguire, of Louisville, Ky., and associates. For years they have been active in the eastern Kentucky field, but only recently started their first western Kentucky development. This strip-mine plant is to have a capacity of 5,000 tons daily, with complete washer, crusher and five-track steel tippie with picking tables and loading boom. It is planned as the largest coal-loading plant in the state. It has been delayed through failure of the Illinois Central R.R. to reach the plant with the new branch line that is now under construction.

The plant of the Sunlight Mining Co., the oldest and one of the best stripping plants in the state, is three miles southeast of Madisonville, on the Louisville & Nashville R.R. This location is 160 miles southwest of Louisville, Ky., and 108 miles northwest of Nashville, Tenn. The company has 500 acres of land and has stripped fifty of these. Its coal lies in two beds on a

1-per cent grade, which makes it easy to drain the pit.

Operations started in August, 1920. The property was carefully prospected in advance. The average thickness of its upper seam, the No. 12 bed, is about 5 ft. This seam is separated from the lower seam, No. 11, by a solid limestone stratum of 3 to 5 ft. The lower, or No. 11 seam, is about 6 ft. thick. Coal from both seams is of good quality for steam or domestic use, measured by western Kentucky standards.

The overburden, which averages from 25 to 35 ft. in thickness but runs up to as much as 50 ft. because of the irregularity of the land, consists of clay and shale. The clay is a little difficult to dig when saturated, but for the most part it is easy to handle.

WORK THE BIG SHOVEL NIGHT AND DAY

A big shovel with 85-ft. boom and 6 cu.yd. dipper started stripping in August, 1920, and has been going steadily since that time, operating with three shifts of eight hours, or twenty-four hours per day part of the time, moving about 120,000 cu.yd. of earth each month. It opened the northwest side of the property with a short cut, following an outcrop. Other cuts were made parallel to this in a gradually increasing curve, so that eventually a complete circle was made around the property to such a distance that the haul from the pit to the tippie is now somewhat more than a quarter of a mile long, the cut being about a half mile long and 100 ft. wide.

Other equipment used includes two smaller loading shovels, working one shift of eight hours a day each. Coal is loaded in ten-car trains, all the cars being of five-ton capacity and fitted for side dumping. Four trains are operated, pulled by 18-ton locomotives. A standard gage locomotive also is used in switching standard railroad coal cars back and forth from tippie to main line. It is reported that the company has not found it necessary to use explosives in moving overburden, but some 40 per cent powder is used on the coal parting. Six drills are kept in operation.

The tippie has a capacity of 2,500 tons daily. Coal from the workings is run over shaker screens, which sort out the 3x6-in. egg and 6-in. block for loading direct to cars, while 3-in. stuff is handled by a belt conveyor to the washing plant, where it is washed and elevated to revolving screens and rescreened to 3x2-in.

Loading Out Strip Coal

Small shovels like this are used for most of this work. Generally the coal is loosened by light shots but in some cases it is lifted by the shovel alone. In this particular plant the overburden was removed in long cuts each 100 ft. wide, following around the edge of the outcrop, the depth of the coal below the surface becoming progressively greater.

egg, 2x1½-in. nut, 1½x3 in. and ¾ in. down. Each size passes under the spray and is loaded into railroad cars, the breakage and slack being flumed back to a settling tank or sump. As many as fourteen men are used at the picking tables, for strip coal must be clean to meet competition.

The company maintains its own machine shop, equipped with forge, welding equipment, etc., to take care of breaks in equipment.

Another feature of the plant is a rock crusher with a capacity of 1,000 cu.yd. a day, operated by the Sunlight Crushed Stone Co., an affiliated concern. The limestone blasted from between the two seams of coal, and lifted by the two loading shovels, is prepared in the crusher for road building, concrete work and the like.

Find Good Coal on Peace River Canyon

THE first authentic account of the Peace River Canyon coal field since the completion of any important exploration appears in Part B of the Canadian Geological Survey's Summary Report for 1922, recently published. The account is written by F. H. McLearn, who spent the full season of 1922 in the district.

The coal field is situated at the junction of the 56th parallel with the 122nd meridian, a few miles west of Hudson's Hope. Those who are not acquainted with the location of this field will be interested to know that it lies 125 miles distant in a direct line northward from the Grand Trunk Pacific R.R. between Edmonton and Prince Rupert, and 324 miles, as the crow flies, from the nearest point on the Pacific Coast. It is about 475 miles due north of the United States boundary. Like the productive coal fields on Vancouver Island and southeastern British Columbia it is of Cretaceous origin. The measures over the area of seven square miles which was examined minutely have a thickness of 1,250 ft. and contain fifty known coal seams, ranging from a few inches up to 4 ft. in thickness. Eleven seams are more than 2½ ft. thick, one is more than 3 ft. and three expand in places to more than 4 ft. Several of the smaller seams are close enough together to be worked as one.

The grade of the coal varies, much of it being excel-

lent. Much interest has been manifested in the Sunlight operations due to the fact that the company was the pioneer in western Kentucky, and it has had enough experience to be an authority, while its methods have been steadily improved upon.

One of the big interests of the stripper people today is to clean their coal so as to counteract the strong prejudice against it. In several western Kentucky operations the top surface of the coal is carefully swept by hand after the overburden has been removed and before the coal is shot up. In at least one instance tractors are employed to drag heavy, four-wheeled rotary steel brushes over the coal. Washing plants and well-manned picking tables also are playing their part, so that western Kentucky strip coal can continue to hold its market.

The Milligan seam, from which the best coal is obtained, averages 2 per cent moisture, 22.5 per cent volatile combustible matter, 73 per cent fixed carbon, and 3.5 per cent ash. The Trojan seam averages about 1 per cent moisture, 26 per cent volatile combustible matter, 63 per cent fixed carbon, and 10 per cent ash.

While admitting that as yet insufficient exploration has been done to enable geologists to make an accurate estimate of the coal content of the field, Mr. McLearn says that sufficient evidence exists to suggest the presence of a total reserve of 84,000,000 tons within an area of seven square miles, and that it is possible that the area and tonnage may be doubled by further exploration.

The field, therefore, is undoubtedly an important one, but cannot be exploited until some better form of transportation than now exists has been provided. At present the nearest railway, the terminus of the Edmonton, Dunvagen, & British Columbia Ry., at Spirit River, is 125 miles distant to the east. This line has been graded to the Alberta-British Columbia boundary, which is 75 miles distant, and the Canadian Pacific Ry. Co. is said to be considering the extension of the line to the coal field and possibly to the Pacific coast. A trial shipment of 42 tons was recently sent down the Peace River to Peace River Crossing, a distance of 300 miles, where its steam-raising qualities will be given a practical test on the Canadian Pacific Ry. engines.

Unusual Hoisting Equipment at Huge German Headframe

Guides Independent of Main Structure and Can Be Adjusted in Case of Subsidence—Protection Against Destruction by Overwinds

By W. BENEDICT

Duisburg, Germany

DURING the past months, when the occupation of the Ruhr brought coal production in that district to a complete standstill, advantage has been taken of the opportunity to make necessary alterations to many colliery installations. A remarkable plant and headframe, the latter being the largest in Germany, and perhaps in the world, has been erected by the Orange Iron Works in Gelsenkirchen for shaft No. 9 of the Consolidation Mining Co. (Bergwerks Actien Gesellschaft "Consolidation"). It is arranged for hoisting in two compartments from a depth of 4,920 ft. (1,500 m.). The rope for hoisting from these profound depths has a calculated breaking strength of 380 tons. The superstructure, 173 ft. 10 in. high, is built in gantry form, with two stays placed opposite each other.

The guide frame, standing between the stays, is so arranged at the top of the structure that it is adjustable independently of the rest of the building. Consequently it is not influenced by the tension of the rope or any possible subsidence of the surface. This arrangement of the guide frame, by which it serves only for the guiding of the cages and is independent of the

stays and the top of the structure, offers a further advantage in that the structure cannot be injured should the rope be broken by an overwind. Furthermore, it provides that damages to the guide frame can be quickly repaired.

On the lower part of the guide frame, immediately below the pit mouth, a runway is constructed, on which are two hand-operated overhead traveling cranes, one behind and the other in front of the structure, which provide for the attachment and detachment of the cages. An ascending and descending platform, 13 ft. above the collar, aids in the quick transference of workmen when changing shifts. In case of a fire and when work is being done over the shaft the opening can be closed by fire trapdoors, these being raised and lowered by means of bracket winches arranged laterally on the structure. A large platform is provided above the roof on which the ropes can be spliced together when being renewed. Below the platform, as far down as the collar of the shaft, the structure is closely covered with plates, so that snow and rain cannot be driven in from the sides. Only water which falls vertically can fall into the shaft.

On the upper part of the guide frame, just beneath the bottom sheaves, a girder structure with platform is arranged, from which repairs can be made and the ropes put in place. The sheave parts can be hoisted up to the height of the sheave platform by a 10-ton crane which is placed above each pair of sheaves. By this means they can be rapidly brought to place in the superstructure. In consequence, interruptions of work when placing ropes on the sheaves and hoisting the latter into place, are reduced to a minimum.

Giant Head Frame with Two Back Stays

Standing nearly 175 ft. above the collar, this Consolidation Mining Co.'s No. 9 headframe provides for hoisting from a depth of nearly 5,000 ft. Novel provisions are made for the removal and replacement of the rope and sheaves and for the caging of the men. The guides are independent of the structure, so that in case of subsidence they can be adjusted to line with the guides in the shaft.

Modernize!—Some Revolutionary Suggestions with Practical Possibilities in Actual Practice

System of Mining by Room-and-Pillar Method with Conveyor Belts from Coal Face to Tipple—Tracks Only for Delivery of Supplies on Storage-Battery Trucks or Locomotives

BY WALTER M. DAKE*

New York City

IN ITS release to the public press of Sept. 24, 1923, the U. S. Coal Commission makes this fundamental statement regarding the necessity of the coal industry cleaning house and lowering the cost of coal to the consumer: "The commission realizes that the largest opportunity and the largest responsibility for putting the coal industry in order lies with the industry itself. Self-determination is the ideal."

It also makes the further statement in exemplification of the foregoing: "Not through governmental coercion but through the enlightened self-interest of producers and consumers the real remedy is to be sought. The coal industry can reform itself from within."

This truism is the essence of the final report and to it need only be added the obvious corollary that the coal operator, while receiving a fair return on his investment, should produce a clean product in sufficient quantity and sell it at a price, regulated by normal competition, such as will give the consumer cheap fuel.

The coal industry is reaching the point where improperly financed and poorly equipped properties operating intermittently and at high cost will be succeeded by financially sound organizations mining immense tonnages at low cost, and this will be accomplished only by the application of modern engineering methods.

Modern engineering has done much for the metal industry. Compare the methods of the early placer mines with those of today. In one the mineral was separated by hand panning or by the use of the cradle and sluice. In the other it is collected and concentrated by a powerful, high-tonnage dredge. Compare also the underground methods of earlier days with the more modern methods. In former years narrow seams of high-grade ore were drilled by hand, blasted and the product treated by stamp mills and amalgamation, only a small percentage of the gold content being recovered. In present-day mines the mineralized rock is obtained by stope mining and concentrated by large-tonnage cyanide mills which make high recoveries at low cost.

In like manner the methods of producing copper, lead and zinc have been improved. Steam shovels, caving systems, fine grinding, flotation and modern methods of smelting and electrolytic refining have been developed and put in operation, showing conclusively the effect of engineering management on mining costs.

Nor is this all; the iron ranges have seen equally startling improvements which have decreased the cost per ton mined and increased the daily tonnage. These changes, with all the subsequent steps of the steel-making process, are the direct result of concentrated engineering effort.

Because an intensive competition is to be anticipated in the coal industry, operators somewhat belatedly are realizing that better engineering is becoming essential in the conduct of their operations. Increased tonnage has lowered the cost of product in industries allied to coal mining and a like increase in output is possible in the production of coal through the extensive use of mechanical labor-saving devices in mining and transportation.

Some such changes already have taken place in coal mines, of which the introduction of coal-loading machinery is among the more recent. These loaders were the subject of an extensive study by the engineering staff of the Coal Commission and observations of performance have been tabulated which show an actual output of 353 tons per eight hours with a loading time of 56 per cent, the remaining 44 per cent being time lost in changing cars, moving loader and incidental delay.

It is understood that one type of loader is being sold under a guarantee of one ton per minute, and this promise of performance is justified by the calculations made from loading records in the field.

Comparing machine and hand loading, an increase of approximately 90 per cent in tons per man per day is noted. This increase is shown with the approximate 44 per cent lost time of machine loading included. The details of these studies were released under the heading, "Underground Management in Bituminous Mines," under date of Oct. 31, 1923.

Taking these facts into consideration, the next improvement in modern coal production must include the loading machine, and its effect on the present system of

A MINE RUN WITHOUT CARS

Locomotives are used solely for taking in timber and supplies, and sometimes running the conveyor backward will take the lighter material to its destination.

*Engineer associated with Sanford E. Thompson in making report on "Underground Management in Bituminous Mines" for U. S. Coal Commission.

CONVEYOR RUNNING STEADILY KEEPS MACHINE BUSY

The conveyor is set in the center of the room so that the machine can the more readily deliver coal to it. Not a moment is lost till the last pound of coal is loaded from the cut.

mining and underground transportation already is the subject of engineering thought and discussion.

At a recent session in a national congress of mining men the chief engineer of a large mining equipment manufacturing concern placed himself on record as follows: "The biggest obstacle in the way of the loading machine is the failure of operators to devise a scheme for getting cars to it fast enough"

This defect has been emphasized wherever the operation of loaders has been studied, and as an efficient system of handling the output of machines calls for drastic departures from recognized procedure and old methods, the operator has been loath to attempt its solution. However, just as the cutting machine, the air and electric drill, permissible explosives, haulage locomotives and rotary car dumps have been gradually adopted as the demand for tonnage has grown so will the loading machine and revised methods of underground haulage come out of an intensification of that demand.

The determining factor of their employment depends on the economic necessity for meeting competitors' lowered cost in the open market. Foreseeing the coming change in underground mining and transportation methods and gathering ideas from both the metal and bituminous fields, a system of mining and transportation for coal production had been devised which indeed embodies nothing new, except in the co-ordination of mechanism already proved effective. This system will increase the tonnage per employee, concentrate the working territory and lower costs to figures unobtainable by present methods.*

Raymond A. Walter, of the Walter Engineering Corporation, has worked out the details of installation and made a primary estimate of costs. The objects of the system may be listed as follows: (1) To adapt a system of cutting, blasting, machine loading and continuous transportation to the type of coal-mining method

now generally employed; (2) to effect the application and co-ordination of already proved equipment to continuous, large tonnage production; (3) to provide automatic control of the continuous system; (4) to provide suitable storage between mine and preparation or loading plant so as to eliminate the usual delays incident to tipple disability and temporary car shortage; (5) to devise equipment installation of sufficient flexibility and durability and at a cost per ton of annual output which will compare favorably with present systems and methods; (6) to effect a saving in cost per ton of output.

In order to accomplish these results the following are necessary in addition to the usual mining equipment, buildings, housing facilities, etc.: Heading machines, undercutters, air or electric drills, loading machines, portable, extensible room conveyors with electric drives, standard conveyor installation, also electrically driven; modern storage bins with reclaiming conveyors and standard tipple or loading equipment.

In order to visualize a continuous operation, the following plan of a mine, opened in a 4-ft. seam under heavy cover, is employed for illustration:

Main and back entries are driven into the seam by heading machines, the product from which is loaded directly onto standard portable extensible conveyors until a sufficient distance has been opened to turn entries to right or left. Portable extensible conveyors are then replaced by standard conveyor belts each mounted on a steel sectionalized base and of sufficient size and speed to carry the desired ultimate output of the mine.

The heading machine then commences operation on the entry and opens sufficient territory to permit seven or eight rooms to be turned on approximately 120-ft.

centers. Portable extensible conveyors in the entry are then replaced by a standard conveyor belt mounted on a steel sectionalized base of sufficient size and speed to carry the desired ultimate output of the entry.

Cutting machines are then used to open rooms 40 ft wide on 120-ft. centers. These are followed by loading machines and standard portable extensible conveyors. With the aid of this equipment the rooms are driven to the desired length.

For illustration, the model mine is operated as follows: Cutting machines are sumped into the coal and a cut is taken across the face. After this cut has been completed, drills are used for placing the holes, which are loaded and shot. Machines mounted on tractors are then moved to the face of the broken coal, and loading commences. The output of the loading machine is continuously discharged onto a portable extensible room conveyor, which in turn delivers to the standard conveyor located in the entry. The entry conveyor in turn delivers the product to the main haulage conveyor, which carries the coal to a distributing conveyor placed above a storage bin of sufficient capacity to receive the entire daily output of the mine.

As each room face is loaded out a cutting machine is moved forward immediately and the operation is carried forward in cycles of cutting, shooting and loading, one cutting machine and one loading machine serving two faces. The conveyors are automatically controlled, so that should the main-line conveyor break down, all others delivering coal from the faces and from the entries are shut down. In case of stoppage of an entry conveyor, only the room conveyors feeding it will be stopped. The stoppage of a room conveyor will affect only that particular operation.

The continuousness of the system is at once apparent, and with a storage bin of sufficient capacity between the mine and tippie there will be no intermittency of mine operation due to delays in preparation and loading disability.

The feasibility of the system can be judged from the performance of cutting machines and mechanical load-

ers under the present method of delivering coal to mine cars.

The practicability of continuous conveyor haulage can be estimated from the performance of standard sectionalized steel extensible trough conveyors, which have been in use for a number of years and can be purchased in any desired lengths with complete drive from manufacturers of coal equipment. These conveyors will be used for all entry advance and retreat, for room and crosscut extension and for pillar work

An estimate of the performance of standard conveyor belts may be obtained from the coal properties where installations are in use and from the record of tonnages of a more abrasive material than coal being carried over great distances—in metal mines and mills. The belts will be mounted on standard troughing and return idlers attached to light steel self-aligning foundation frames which will permit the replacing of temporary steel trough conveyors by the addition of the necessary number of foundation frames and of an extra footage of belting and by the moving of the tail pulley to the desired point in the main slope to reach newly opened right or left entries, or in entries to permit the discharge of tonnage from newly opened rooms.

The retreat from destination crosscuts and from room- and chain-pillar operation is accomplished by the reversal of the advancing method of installing conveyors. All semi-permanent conveyors are suitably an-

operation where either the car or conveyor method of underground transportation is in use.

Through the use of this system of mining the working faces can be concentrated to such a degree that it will be possible thoroughly to supervise their operation.

By the use of this method such speed in advance and retreat is obtainable that it is possible to open and recover a higher percentage of coal from any given area

than by any other method, thus avoiding the usual sloughing and caving accompanying slower extraction. When the model property used for illustration is opened sufficiently to allow the continued work in seven rooms, four rooms advancing and three pillars retreating on two entries, 666 tons per shift can be delivered from approximately 960 ft. of entry in 4-ft. coal. This gives a total tonnage per lineal foot of entry approximately twice as great per shift as can be produced by the usual method of room-and-pillar mining.

As the system calls for the elimination of all contract labor and the substitution of employees of higher quality for a completely mechanized operation from face to railroad cars, all workmen are placed on a daily wage basis. With this accomplishment it will be possible to operate the property three shifts per day, thereby multiplying the tonnage per lineal foot of entry produced by the usual method of room-and-pillar mining by a factor of approximately six. This also will lower the equipment cost and interest charges per ton of annual output by two-thirds over the present method of single-shift operation.

By the use of the system all car dumps, cars, rails, bonds, switches, ties, electric locomotives, trolley wires and rope haulage are eliminated in the actual transportation of coal from the face. Light track and storage-battery locomotives can be installed for the handling of heavy material or storage-battery trucks can be utilized where conditions are favorable. For light material the room conveyors may be reversed and used for carrying supplies to the face.

As it will not be necessary to remove cutting and loading machines from a particular section of the mine until rooms have been driven and pillars pulled, the delay caused by the present method of shifting these units almost hourly from one part of the mine to another also will be eliminated.

In order to carry out the comparison of present and

HOW COAL IS DUMPED INTO STORAGE BINS
Enough storage is provided to satisfy a day's run. At the mines much time is lost because one operation waits on another leading up to it or following from it. The bin smooths out these delays.

proposed systems of mining to a more definite point an estimate of the complete cost of installation for a property producing 4,000 tons daily from a 4-ft. seam of coal is given; see Tables I, II and III.

Provided the property is leased instead of purchased \$2,000,000 will finance its development and operation at a daily output of 4,000 tons. To attain this low investment temporary buildings and equipment are substituted for the permanent ones. Taking the flat figure of \$2,000,000 for total estimate of plant, equipment and carrying charge until full operation and basing the production on a 4,000-ton daily output for 250 days per year, a total annual output of 1,000,000 tons is indicated. This gives a figure of \$2 per ton of annual output, which compares most favorably with the lowest investment cost of the lowest present-day operation.

Estimating further, the detailed cost of operation is given in Table IV.

The commissary should show a profit to absorb the loss on house rentals. Table X is the suggested cost.

The profit from commissary operation is then thrown into the camp fund, Table XI, which is self-explanatory.

Referring to the estimated total organization, it is to be noted that the number of employees on the roll is 368, or approximately one-third the number necessary for present-day operation of the same tonnage output. The inside organization produces 16.5 tons per employee per day, which figure has been equalled, but is decidedly unusual in present-day practice. For total employees on production an output of 12.5 tons is indicated and for total employees 11.7 tons per day.

For the purpose of this estimate it is to be noted that

TABLE X—PROFITS AND COSTS OF OPERATION OF COMMISSARY		
Estimated at \$300,000 gross sales annually.

	\$82,436
Annual profit	\$1,956

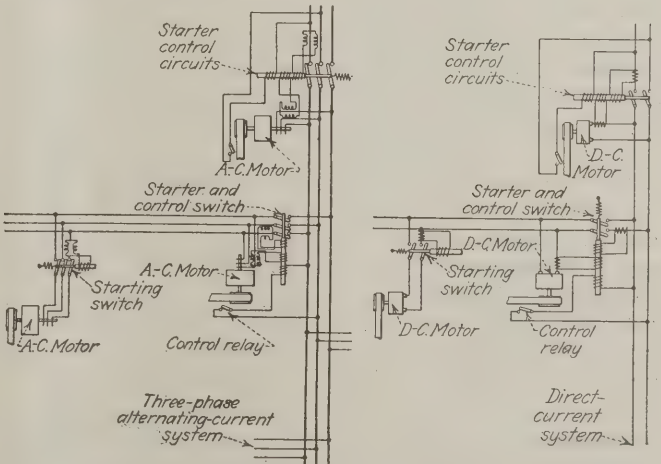

TABLE XII—ESTIMATED COST OF PRODUCTION

Wages and salaries (total mining)	\$0.5984
Supplies	.3000
General Expenses:	
Administration and office	\$0.0760
Insurance (general)	.0025
Insurance (compensation)	.0150
Taxes (excluding Federal)	.1000
Depreciation	.0500
Depletion or royalty	.0550
	.2985
Total cost	\$1.1969

the minimum day wage for mining operative labor is figured at \$7.50 per 8-hour shift, and that salaried employees range from \$1,200 to a minimum of \$150 per month. Computing from these rates, a total mining cost of wages and salaries equals \$0.5984 per ton. Adding to this amount a flat estimate of \$0.30 per ton for supplies, and a total of \$0.2985 per ton for administration, etc., the remarkably low total cost of \$1.1969 per ton is indicated.

With the production of prepared sizes of bituminous coal at \$1.1969 f.o.b. cars and with selling cost added, coal can be delivered to consumers at prices ranging so far below present average cost that the entire annual capacity output could be sold and a stabilized profit realized at a selling figure much lower than could be attained by competitors. This low price would eventually be reflected to the consumer by the increasing use of low-cost production systems, and the general public benefited through engineering management and modern engineering methods

“Not through governmental coercion but through the enlightened self-interest of producers and consumers the real remedy is to be sought. The coal industry can reform itself from within.”

TWO SYSTEMS—ALTERNATING AND DIRECT CURRENT

In any system arrangements must be made that no conveyor will deliver onto a stopped or stalled conveyor. When a conveyor stops, all conveyors feeding it directly or indirectly must be stopped also.

A Tribute to a Notable Editor

BY R. DAWSON HALL
Engineering Editor, *Coal Age*

C. E. LESHER, till recently editor of *Coal Age*, had in the short time he filled that office given evidence of an unusual fitness for the exercise of that function. His resignation to become assistant to the President of the Pittsburgh Coal Co. came as a surprise to his many friends and associates, for they were but little disposed to believe he would cast aside a profession that fitted him so well and was so in accord with his preferences and qualifications.

He came to *Coal Age* with a wide knowledge of the coal industry acquired in many years of statistical and administrative work in the government service. For many years

he was a geologist in charge of coal statistics, in which work he made notable innovations, including the weekly report. He understood the value of speed in the distribution of the data of operation—a quality of inestimable value in his later practice of journalism.

Mr. Leshner is a native of Colorado and obtained his technical education at the Colorado School of Mines, being graduated in 1908. His two years in the work-a-day metal-mining field, of which he had many fond remembrances, freed him from an aloofness of attitude toward operating problems that government employees are supposed to have. Later he was engaged by the American Nitrogen Co. In 1910 he joined the staff of the U. S. Geological Survey, and, strangely enough, aligned his career with coal and not with the metals. For two and a half years he was chairman of the coal board of the Survey making geological investigations into the coal fields of many states.

On E. W. Parker becoming director of the Anthracite Bureau of Information and leaving the Survey, Mr. Leshner succeeded him. Coal problems becoming acute in 1917, he was detailed to the Fuel Administration, being director of its Bureau of Statistics until June, 1919, and in the exercise of his duties became acquainted with the leading coal executives of the country, who admired his good judgment and his stalwart integrity. Returning to the Geological Survey for a short period he later—during the 1919 strike—became a member of the Central Coal Committee. Then followed in 1920 his period of active service for the National Coal Association, in which he organized its Bureau of Economics.

In April of that year, however, he left the association to become editor of *Coal Age*, during which he made important changes in the character of the paper. His tabulations and curves of coal prices, culminating in his index, his orderly presentation of marketing facts, his news-gathering ability, his editorials, redolent rather

C. E. LESHER

of the field than the office, added to the standing of the publication and made him an outstanding figure in the industry. Thus fortified by talent and experience, a restless but well disciplined mind, a marvelous knowledge of the men and the material of the industry and a diplomacy and *savoir faire* only equalled by his integrity of purpose, he brings to the Pittsburgh Coal Co. constructive qualities which that corporation will not fail to find immensely valuable in the handling of its big enterprises. The good wishes of the staff of *Coal Age* accompany him.

Engineers Study Economy in Fuel Use

DESIGNING, operating and fuel engineers of the railroads, public utilities, manufacturing interests, colleges and coal sales companies of the country met Jan. 15 at the Engineers' Club, Philadelphia, Pa., and discussed economy in the use of fuel.

G. M. Basford, consulting engineer, of New York, read a paper entitled "Recent Accomplishments in the Improvement of Power and Efficiency of Steam Locomotives." Other papers and discussions that followed pointed out how large economies could be effected by the use of better designed locomotives. The latest developments along this line have been more scientific design of boilers, adoption of stokers, superheaters, feed-water heaters and boosters. By the use of these improvements it has been possible to generate energy at the rate of 1.8 lb. of coal per horsepower-hour. It was asserted that about one-fourth of the coal supply of the country is used by the railroads, and the losses amount to about 30 per cent of the total quantity used. They said great savings could be effected by reducing idle time and by more careful firing under operation and while standing idle at the roundhouse or terminal.

The afternoon session was devoted to public utilities and manufacturing plants, when the subject was discussed principally by representatives of power plants and metallurgical interests. At this session Morris L. Cooke, consulting engineer, of Philadelphia, outlined the Pennsylvania giant power survey, the purpose of which is to conserve coal, first, by the development of large power-generating stations located at or near the mines and interconnected into a large system; second, by the development of the byproduct industries, and third, by savings effected by serving small producers of power with energy from a large system.

N. G. Reinecker, of the Pennsylvania Power & Light Co., showed how his company had found that interconnection of power plants had materially reduced the investment, operating and fuel costs per kilowatt-hour of energy developed. The load is so distributed that plants capable of generating energy at lowest costs are generally loaded up as near as possible to capacity. Stand-by charges can be materially reduced, and it is not necessary that generators be started and stopped at every slight indication of an increase or decrease of load.

H. O. Loebell, vice president of Henry L. Doherty & Co., discussed the possibilities of large coal savings in domestic use by the greater appreciation of gas as a heating medium. He asserted that by a careful revision of the law it would be possible for companies to produce gas for heating purposes at efficiencies between 70 and 80 per cent as compared with the operation of domestic furnaces at from 5 to 20 per cent.

Too Much Around a Coal Mine Is Left to Chance

Mechanical Weakness, Improper Design and Haulage Delays Lower Output 10 per Cent at Tipple Capable of Handling 7,390 Tons Daily—Rarely Is Supervision Close Enough to Provide for Standardization and Correlation of Activities

CLOSER study at coal mines to develop standard methods of performing operations and to eliminate lost motion and delays would increase output without changing equipment or adding materially to the personnel. Every operation should be given an intensive study both to develop the best method of performing the work involved and to fit its performance into the complete combination of effort by which coal is brought to the surface and dumped into railroad cars for shipment.

Production Losses at Tipple.—Fig. 1 shows the number of pit cars dumped by fifteen-minute periods for one day at one of the larger mines. It is presented as illustrating not so much the time losses at a single mine as the losses that are common in a large number of bituminous mines but which are not appreciated.

Production losses from four causes are shown. Approximately 6,000 tons of coal was hoisted and dumped at this tipple on the day observed, and although this was a relatively high day's production for that particular mine, and considered to be its maximum, it shows the tipple to have been operating at only 81 per cent of its capacity. The loss of 84 cars or 360 tons production due to major mechanical difficulties is a type of loss that cannot be entirely eliminated in any type of machinery subjected to the severe usage that tipple and hoisting equipment undergo, and a certain time loss, therefore, must be anticipated when designing the tipple arrangements.

The loss of 157 cars, or 670 tons of production, was, however, due to a type of mechanical difficulty which occurred over and over again, day after day, viz.: the incomplete discharge of the car at the first dumping. Yet no thought was being given to an improvement in

the mechanical process of dumping that would eliminate this large loss.

It is true that under almost any condition an occasional failure would be possible, but when these failures are identical in character and are sufficiently continuous to cause a loss in production of 670 tons, or over 10 per cent of the whole output, and are allowed to continue, it is evident that the elementary principles of management engineering that are coming to be employed so generally in other industries are not being applied in this instance.

TIPPLE STOPS EVERY TIME LOADER IS DOCKED

A loss of 37 cars, or 160 tons, was due to defective tipple design, it being necessary to stop hoisting whenever a car containing rock was dumped, in order to remove this rock and to dock the miner for loading it. Realizing that the losses from this cause were unnecessary the management were redesigning their tipple so that any such car of coal would be inspected and cleaned automatically on a separate table, leaving the regular tipple operations to be continued without interruption. Though this method was employed in some of the mines with the most advanced management and technical staff it was not found to be in general use.

A further loss of 48 cars, or 200 tons was due to defects in the underground-haulage methods. It represents the loss due to the absence of loaded cars at the shaft bottom at times when the hoist was ready to operate. This loss would have been much larger if the previously mentioned causes had not stopped hoisting and during that time permitted loaded cars to accumulate at the bottom.

Sixth installment of report on "Underground Management in Bituminous Mines," made by Sanford E. Thompson and Associates to the U. S. Coal Commission. Previous installments may be found in Vol. 24, pp. 691, 733, 773, 811 and 845. Other sections of this interesting report will follow later. The introductory paragraph of this section is added to the original to serve as an introduction to what follows.

Supervision Underground.—The relation of the number of assistant foremen or face bosses directly in charge of underground work to the number of men under their control is shown for several mines in Table I. The relation of tonnage, or piece-rate, workers to company men or day workers, differs materially, but

TABLE I—RELATIVE NUMBER OF WORKERS TO BOSSES

Designation of Mine	DS	RZ	TS	RM	TP	HI.
Total number of face bosses or section foremen	2	4	3	6	6	47
Total company men inside	83	190	52	94	205	553
Total tonnage workers (loaders and cutters)	268	450	122	194	153	889
Company men per boss	41	48	17	16	34	12
Miners per boss	134	112	41	32	25	19
Total men underground per boss	175	160	58	48	59	31

that is inevitable because of the difference in the physical condition of the different mines. But the ratio of underground workers to foremen and face bosses is not so readily explained when one stops to consider that in the case of mine DS, for example, the 175 men are scattered over a distance of more than a mile and a half underground, and the several workers separated from each other by distances of from 100 to 300 ft. When it is remembered that one man directly supervises their work it is easy to comprehend one of the reasons why the work is not standardized and correlated.

The standardization of a miner's work, as will be discussed later, involves two things: (1) The standardization of the method and time of the individual items of his work, and (2) the correlation of these items in such a way that the lost time both to himself and those other men whom his work affects will be reduced to a minimum.

The solution of the problem, as has been indicated already, is not necessarily more foremen of the present type, but more thorough training of these men such as is being given them in a few mines, and above all an organization based on modern industrial lines with functional supervision, not limiting the officials to the executive function but including as officials men trained to handle certain other principal elements such as haulage, planning the work of the men, and standards of production.

IN A MINE, WORK OF ONE SETS PACE FOR ALL

Correlation of Mining Operations.—The correlation of haulage with the work of the miner has been discussed in previous articles. Similar principles apply to other mining operations.

The work of all classes of men in a coal mine is interdependent. If a machine cutter fails to cut a loader's place the loader may be forced to stop work. If a tracklayer is behind in laying a switch it delays the opening of a room. If a timberman fails to set timbers quickly enough when needed at a certain place, and a fall occurs, it may disorganize the work of all the men in that section for several hours. The failure of a shotfirer to shoot a place at the proper time stops or delays the loaders and slows up the haulage.

When the loader in turn quits and goes home early without cleaning up his coal, it affects not only himself but the machine cutter, tracklayers and drivers, whose work is disorganized.

A loader's work covers in general other things besides the actual loading of coal. In some cases he lays his track (ties and rails), pushes his car to the face, sets timbers, loads or gobs slate, drills, snubs, loads and fires shots and loads his coal. In other cases he does almost nothing but load coal, everything else being done for him. The majority of cases lie somewhere between these two. No one has taken the trouble to ascertain the relative proportion of the miner's time necessary under normal conditions to perform the varied parts of this work.

All of these things and their variety show the need

FIG. 1—NUMBER OF MINE CARS DUMPED AT TIPPLE BY 15-MINUTE PERIODS

Car losses have been figured by pro-rating the time lost on a basis of 54 cars per 15-minute period. The cars dumped in 15-minute periods were actually 1,402 cars. Averaging 4.28 tons capacity without delays 1,728 cars would have been dumped. The tippie was operating at only 81.2 per cent of the hoisting capacity.

for a modification of the scheme of management in line with that toward which some of the most up-to-date mines are already tending and which are exemplified still further in certain metal mines.

At present this definite control of the work of the loaders and company men is made impracticable by lack of knowledge of the time that it should take to do different classes of work. It is recognized that physical conditions present greater variety and affect operation much more definitely than in most manufacturing industries, the standards of production of which have been determined. As will be shown later, however, this division of the subject can be treated in detail, for it must be remembered that in metal mines, where operations are equally varied, they have been carefully standardized. This fact shows the possibilities of determining standards of production which will make possible a more scientific control of operations, thereby saving in operating costs and affording benefits to the workers.

In many of the mines visited, the foremen, superintendent and general manager were asked for estimates as to the time necessary to perform various types of work. Their replies varied from 10 to 45 minutes for the same operation. A member of the pit committee estimated that this same operation could be completed in two hours. They were all guessing and in the replies given favored their side of the matter. This was quite natural, but the point that should be emphasized is that the actual facts were unknown.

The same conditions exist with respect to the work of the company men, the tracklayers, timbermen, etc. Differences in estimates of the time required for any given piece of work generally varied more than 50 per cent.

FULL INFORMATION regarding the chemical composition of coal of the Twentymile Park district of Colorado and its heating value as determined by the U. S. Bureau of Mines is given in Bulletin 748 of the Geological Survey. This value is compared with the heating values of competing, or possibly competing, coals, so that the consumer, if he cares to do so, may balance one coal against another and thus be able to select that which will give the greatest return for his money.

Mine-Rescue Communication System of the Future

Results of Actual Mine Experiments—High- and Low-Frequency Penetration—Modified Wired Radio Seems to Hold Greatest Possibilities

BY J. J. JAKOSKY
U. S. Bureau of Mines

FOR ordinary purposes, the present mine telephone, although somewhat costly in initial installation and maintenance, is giving satisfaction in most mines. In case of a disaster, such as an explosion, fire, fall of rock, flooding, etc., the telephone is one of the first instruments that usually is put out of commission, and at the time when it is most urgently needed. On this account the mining industry as a whole is interested in any system of communication—phone in preference to code—that can be relied upon in an emergency, and many requests have been received by the Bureau of Mines to devise such a system.

The solution of the mine-communication problem is dependent mainly upon the working out of a practical portable mine apparatus of sufficient sensitivity for receiving and transmitting at effective ranges. It is well known that signals can be transmitted considerable distances through the earth if sufficient power and a receiving set of sufficient sensitivity be used.

REQUIREMENTS FOR MINE-RESCUE RADIO

The ideal system for mine-rescue work and general underground communication would be one where voice transmission and reception is possible. This is the ultimate end as a solution; but if such a system is not immediately possible or conveniently portable, then a simpler system where a telegraphic code or prearranged signals may be employed is desired. The transmission of code cannot be considered as a general solution to the problem of underground communication. Code, however, has advantages as regards transmission of information, over the geophone.

A practical type of apparatus for underground communication will have to be simple in operation. If high frequencies are used, requiring tuning to produce resonance, some fixed wave-length should be used. Vacuum tubes are the only practical method for the successful modulation and transmission of voice signals. For the transmission of code signals many different instruments can be used.

The apparatus will have to be safe to use in an explosive gaseous atmosphere. During mine disasters, and especially when barricades are erected, there is great probability of danger from a gas explosion if unsafe electrical apparatus be used. All mine-signal apparatus should be of an approved and permissible type.

CONSTRUCTION AND DETAILS

For satisfactory and practical use in mining and rescue operations, an underground signal apparatus probably would have to be designed to incorporate the following points:

(1) The apparatus must be moisture- and waterproof—that is, it should be unaffected by dampness

and continuous standing in wet mines. In this connection it may be stated that practically none of the radio or high-frequency apparatus being sold today would be suitable for such work. The condensation of moisture on the surfaces of dielectric and non-waterproofed insulating materials, unprotected windings, condensers, etc., causes large current leakages. In one of our tests a radio receiving set which had been left underground for about six hours became very inefficient.

(2) The apparatus must be durable, rugged and fool-proof. The entire equipment should be enclosed in a strong case, and all delicate apparatus such as vacuum tubes, controller knobs, etc., should be protected.

(3) A practical mine apparatus should be easy to maintain in good working order. Depreciation of the apparatus itself is of importance, and also care must be given to any batteries which may be used. Batteries should be given regular inspection.

(4) The receiving apparatus will have to be simple to operate and probably will have to be very sensitive. In practically all types of underground communication, whether by direct ground, induction currents, radio, and to a much less extent wired wireless, there is high absorption of the transmitting current. The energy picked up by the receiving apparatus is only an infinitely small part of the energy transmitted, thus requiring a very sensitive receiving apparatus.

(5) The last and probably most important point to be considered is the weight and shape of the signal apparatus. The weight must be kept below about 40 lb. if the apparatus is to be sufficiently portable for underground use. It is possible that a satisfactory design will be worked out wherein the transmitting and receiving apparatus is contained in one cabinet, and the power supply, whether batteries or hand-cranked generator, contained in another cabinet. A suitable non-reversible plug, safe in explosive gaseous atmospheres, could be used for connecting the power supply to the apparatus when in use. The general shape of the enclosing case and carrying straps or handles must be such as to allow the apparatus to be readily moved should it be necessary to crawl or keep one hand free.

METHODS BEING INVESTIGATED

The present investigation being conducted by the Bureau of Mines includes studies of the following systems: (1) The T.P.S., or ground-conduction, method; (2) induction signaling, both high and low frequencies; (3) wired radio over underground mine power and telephone lines, trolley wires, rails, and through piping for water and compressed air; (4) radio; and (5) electrical geophone and auxiliary signal equipment. These investigations include studies of the effects of rock falls, mine flooding, and similar conditions encountered during disaster, as well as general underground conditions existing in the ordinary operations of metal and coal mines.

SUMMARY OF INVESTIGATIONS BY BUREAU OF MINES

Little difficulty was encountered in transmitting T.P.S. signals to distances of 1,200 ft. over compressed-air piping, car rails, or other conductors to any part of the Bureau's Experimental Mine. In these tests a short direct connection is made with the rails or pipes. There is a decrease in audibility with the distance between stations. In the transmission along mine tracks, mud and water over the tracks, switches and breaks in

the tracks, did not prevent exchange of signals. In two places, 8-in. wooden rails had been inserted as a protection against lightning, and the T.P.S. signals carried through the wooden rails, which were moist, without any great decrease in audibility.

In order to determine the effects of mine cars on the track, a mule was hitched to two pit cars and a truck. The transmitting set was placed at the rear of the mine, about 1,200 ft. from the entry where the receiving set was placed. Signals could be transmitted without difficulty, and it is interesting to note that the audibility of the received signals was low when the mine cars are near either the transmitting or receiving sets, but as the distance between these sets and the cars is increased, the audibility rises considerably. In vertical transmission tests the T.P.S. set was placed in the mine 600 ft. from the entry. Ground leads extending 100 ft. each way from the set were used, one lead going to ground 500 ft. from the entry and the other lead placed 700 ft. from the entry. Because of the narrowness of the entry, the ground plates, which were laid upon the mine floor, were placed within 3 ft. of the car rails.

UNDERGROUND TESTS CARRIED OUT SUCCESSFULLY

The Bureau's mine is a drift mine having about 160 ft. of overburden at the end of the drift, which is 1,300 ft. long. The receiving set was placed on the surface as near over the T.P.S. set as possible to estimate, the ground leads extending approximately parallel to the leads within the mine. Little difficulty was had in transmitting signals from within the mine to the surface, and signals could still be transmitted when the surface receiving set had been moved—still keeping ground leads parallel—to a point more than 800 ft. away from a point on the surface directly above the transmitting station.

Similar tests were carried out at the Pittsburgh Terminal Coal Co.'s Mine No. 3. This mine is a shaft mine about 250 ft. deep. Little difficulty was met in transmitting T.P.S. signals from the mine to the surface. A heavy rain fell during the first part of these tests and the receiving apparatus was not removed from the automobile. Two 100-ft. ground leads were run in opposite directions to the side of the road and code messages easily were received from the mine. The heavy rain and water covering the road did not prevent the T.P.S. set from working.

During the second day of the tests the ground was covered with about 3 in. of snow, and as before, code messages could be readily received. These tests were made with the surface ground terminals approximately parallel to those underground. Later tests, where the terminals were placed approximately at right angles, showed a marked decrease in signal strength, indicating, as had been found in the tests at our Experimental Mine, that the two ground terminals should be approximately parallel for maximum signal strength. In the track transmission tests, an abandoned section of track was used. The track was covered with roof falls practically its entire length and water varying in depth from a few inches to a foot covered many portions of the track. The dirt and water covering the rails did not appreciably affect the transmission of code, and results practically similar to those at our Experimental Mine were obtained.

The code T.P.S. set, while rugged in construction and extremely simple to operate, cannot be considered as a practical solution of the underground-communication

problem because of its being limited to the use of code alone. Present investigation being conducted by the Bureau of Mines is on a method of changing from the present T.P.S. code set to a similar type of apparatus capable of transmitting directly voice communication. These experiments are in progress at the present time.

Preliminary radio field work at the Bureau's Experimental Mine was done during the summer of 1922 by C. L. Colburn, C. M. Bouton and H. B. Freeman in conjunction with engineers from the Westinghouse Electric & Manufacturing Co. For this work a Westinghouse 20-watt transmitter and a single-circuit regenerative receiver was used.

WAVES PENETRATE HEAVY STRATA

Recent tests made at the Bureau's Experimental Mine may be of interest as they indicate the great attenuation of waves in penetrating the earth. In these tests a special 3-step radio frequency detector and 2-step audio-frequency set, with a 14-in. loop aerial was used. At the mine entry signals from KDKA and WCAN (about 10 miles away) could be heard over 100 ft. from the phones. The set was mounted on a mine car and audibility readings taken every 100 ft. as the car was pushed into the mine. The audibility dropped very rapidly the first 50 ft. and decreased more slowly thereafter until the signals faded out at a distance of 700 ft. from the entry. The directional property of the loop was maintained underground. The loop also has advantages in minimizing ground currents and induction effects.

While unsuccessful in indicating any practical method of using wireless for underground communication, these experiments, nevertheless, indicate clearly that electro-magnetic waves may be made to travel through solid strata. The absorption or loss of intensity with distance was very great for the high frequencies (short wave lengths) used in these experiments. It is known, however, that lower frequencies suffer less attenuation and absorption, and these may possibly be found effective under certain conditions.

SHORT WAVE LENGTHS SEEM BEST

The energy radiated from the antenna decreases, however, with the use of low frequencies. For general underground use, a large antenna is impracticable. The shorter the antenna, the higher must be the frequency in order to operate the antenna somewhere near its fundamental—at which point maximum radiation, for a given power input, is obtained. A compromise probably will have to be reached between wave length and the distance to be transmitted in order to obtain the maximum efficiency from the apparatus for mine communication service.

As a summary the present available data indicate that the most practical type of mine-communication apparatus will be a modification of wired radio utilizing compressed air or water piping, car rails, etc., as the conducting medium. Dirt and water over such conductors, and numerous breaks in the metallic circuit, do not appear to prevent the transmission of signals. In such a system, much simpler transmitting and receiving apparatus can be used. As to whether a voice-modulated high-voltage direct-current transmitting set or a high-frequency voice-modulated carrier wave set is to be used will depend upon future experiments.

Induction and Synchronous Features in New Motor

Design Embodying Best Characteristics of Both Types
Combines High Efficiency, High Torque, Constant Speed and High Power Factor

THE induction motor is one of the simplest types of electric motors, possessing characteristics that are highly desirable for many different types of drive. Its speed control, torque, size and ease of repair are important advantages in its favor, but it has the disadvantage of inherently operating at a poor power factor; in fact, on light loads the power factor often is as low as 20 per cent, and as most drives do not always operate at full load, the average power factor of many induction motors may often be as low as 50 or 60 per cent.

During and since the war changes in power schedules have revolved around the subject of power factor. Many power schedules have been put into effect penalizing the consumer for operating at low power factor. When we consider the large investment that the power company must make in generating and transmitting equipment to furnish loads with poor power factor, the justification of such penalties must be admitted. If the consumer is generating power for himself he is confronted with the same problems. Therefore it is important that the user of power operate at as high a power factor as possible.

One of the biggest problems of the manufacturers of electric motors has been to design a motor which would have the good characteristics of the induction motor and also the good characteristics of the synchronous motor. The squirrel-cage type induction motor develops a very high torque if the resistance of its rotor winding is high, but under these conditions the motor operates at low efficiency. It is possible to raise the efficiency of the motor by lowering the rotor resistance, but when this is done a low starting torque results. Synchronous motors have the advantage of operating at constant speed but usually have low starting torque and low pull-in torque.

To combine high efficiency, high torque characteristics, constant speed and high power factor, the Wagner Electric Corporation of St. Louis, Mo., has developed the Fynn-Weichsel motor. This motor is essentially a combination of the induction motor and synchronous motor. The usual rotor winding of an induction motor is placed on the frame and called the stator. The usual stator winding is placed on the revolving member, commonly known as the rotor. In addition, the revolving member has a winding which is essentially a synchronous-motor exciting field. These two windings

FIG. 1—ROTOR WITH STATOR AND EXCITING FIELD WINDING

The stator winding gives induction-motor characteristics and the exciting field winding gives synchronous-motor characteristics.

FIG. 2—CHARACTERISTIC CURVES OF NEW MOTOR

are respectively connected to slip rings and a commutator mounted on the rotor shaft. Power is applied to the slip rings of the revolving member, and resistance is placed in the stator winding to regulate the speed. This is quite similar to the wound-rotor type of induction motor, excepting that the power is supplied to the rotor and the control resistance is in the stator winding.

The operation of the motor is such that it starts out as an induction motor and, therefore, has induction motor characteristics, comes up to synchronous speed and operates as a synchronous motor, and under very heavy loads pulls out of synchronism and again automatically becomes an induction motor with high pull-out torque. During starting, when the motor operates as a regular slip-ring induction motor, it will develop 150 per cent full-load torque and still increase in speed up to synchronous speed and may be started in this manner under load, as the usual slip-ring induction motor, by cutting out resistance in the secondary circuit. The motor can speed up to synchronous speed with as much as 150 per cent of rated load. At synchronous speed it becomes a self-excited synchronous motor by the functioning of its exciting field winding mounted on the revolving member. If loaded beyond 160 per cent full load the motor is again pulled out of step and continues to operate as a slip-ring induction motor until the load exceeds 300 per cent full load rating, when the motor pulls out and stalls.

It will be noticed from the characteristic curve diagram that the power factor of this motor after being brought up to synchronous speed, is 65 per cent leading at no-load and continues to lead until the load has been increased to 160 per cent. Here it suddenly drops to a lagging power factor and is similar to the induction-motor power-factor curve from this point up to about 300 per cent full load. The speed is constant from no-load up to 160 per cent load and then drops off slightly until 300 per cent load is reached. The line current at 160 per cent load suddenly increases, as we would expect, because the power factor has suddenly changed from unity to lagging. An important point, however, is the fact that the efficiency curve is high over the whole range of load from 0 up to the point where the motor actually stalls; even at 25 per cent load the efficiency is about 72 per cent.

The application of this motor to correct lagging power

factor on lines having heavy induction motor loads is very important, but more important is the fact that it can be applied to loads requiring a motor with induction-motor characteristics and at the same time correct power factor or maintain the power factor very close to unity. Under these conditions it is far better than any other power factor corrective equipment because it maintains high power factors on all lines to which it is applied instead of letting the power factor become very bad and then correcting it somewhere back on the line where the advantage is only passed on to the power company or the local generator power station.

The installation costs of heavy lines, switches and transformer equipment, which are considerably increased in size in order to carry heavy wattless currents, can be materially reduced by maintaining power factors nearer unity. There also is another important item which is not always considered and that is the cost of circulating this high wattless current through the lines and its resulting high power losses.

Ohio Uses as Much Coal as It Mines

The most important coal bed in Ohio, according to Technical Paper 344, "Analyses of Ohio Coals," just issued by the Bureau of Mines, doubtless is the Middle Kittanning, which because of the quality of its coal has made the Hocking Valley famous throughout the country. The Pittsburgh coal bed probably is a close second and is mined extensively in Belmont and Jefferson counties. Other beds have attained prominence in local fields, but the two mentioned above must be regarded as furnishing the bulk of the coal produced in Ohio.

In a chapter on "Mining and Transportation of Ohio Coals," by J. W. Paul, chief coal-mining engineer of the Bureau of Mines, it is stated that the methods of mining the different beds of coal in Ohio are, in general, the same throughout the different coal-producing counties, consisting mainly of the room-and-pillar plan. In a few mines the rooms are driven in panels.

Because of the practice of not removing the room pillars the percentage of recovery of coal in Ohio has not been much over 50 to 60 per cent. The practice has been to leave the pillars as long wedges, widest near the mouths of the rooms and gradually narrowing toward their faces. In the Steubenville district the Freeport bed has been successfully mined by longwall.

The coal fields of Ohio are well served by a number of railroads. The Ohio River affords water transportation for some mines along its course, but the quantity thus shipped is only a small part of the output of the state. There are two principal fields in Ohio—the northern, which produces about 65 to 70 per cent, and the southern, producing 30 to 35 per cent of the state's total.

About 40 to 43 per cent of the total output of the mines is consumed within the state limits, 5 to 9 per cent is shipped to other states and 48 to 55 per cent embraces the tonnage delivered to railroads, exported by rail, or shipped to tidewater and to the Great Lakes for cargo.

Although the mines ship a large tonnage to other states, Ohio receives so much coal from beyond its borders that the consumption within the state, exclusive of railroad fuel, is equal to the annual production.

Technical paper 344 is the third of a series of papers issued by the Bureau of Mines, No. 269 referring to Iowa and No. 307 to the Kentucky coals.

The Miner's Torch

Is He the Absolute Boss?

YEARs ago, while I was a coal-mine superintendent, I was once a guest at a Chamber of Commerce dinner in a near-by city, and I was the only coal-mining man present. In introducing me the toastmaster remarked rather felicitously that I probably was the only "absolute boss" present. Of course, he had in mind company dwellings, commissaries, etc.

I first recalled that introduction in 1918. The government was moving heaven and earth in an endeavor to get the miners to speed up and dig more coal, because all of the essential industries were rapidly approaching a point where further increases in production were directly dependent on more coal. By way of doing "my bit" I attempted a series of articles appealing to the patriotism of the miners. As I was not in direct touch with miners or mines at that time I made several trips to mining camps in search of inspiration for the articles.

On one of these visits I met a superintendent who had a son in the trenches overseas, from whom he had had no word in over a month, and in consequence was on the verge of nervous collapse. "If only I could do something to help win the war I would not feel so bad," he said to me, "but in spite of all of my pleading with my men I cannot get them to work every day and on the days they do work they refuse to speed up. And most of these men know my son too."

And last week it came back to me again that remark about the "absolute boss." Once more I was at a mining camp and this time a superintendent was telling me of the Christmas plans of his men. "We have been working only two and three days a week lately and our miners are having about all they can do to keep the wolf from the door, but they can't think of disappointing the kids nevertheless," was the way he put it.

"Do you know, Thompson," he said to me, "I have only recently begun to realize how little authority a coal-mine superintendent really has. Every day the men report for work and one time they are met with the notice 'No work today' and again the notice says 'Work today.' Now how much do I have to do with the wording on that notice? Absolutely nothing. The city office checks up orders and gives us our instructions just as promptly as possible, and we in turn pass the information on down the line.

"With this desire to give the kids all they are looking for, it's pretty hard for the ones who have large families to make the best of present conditions and it's touching to see the disappointment registered on their faces when the notice points to an idle day. When I am around they come up to me and tell me all their troubles and it's plain to see that they think that I might change conditions if only I'd try hard enough.

"Of course, last year the shoe was pinching on the other foot and the city office was wondering why in thunder I couldn't get out more coal, considering all of the money I had spent for new equipment and that I didn't have a vacant house in my camp."

Yes, the coal-mine superintendent is an absolute boss.(?)

News Of the Industry

Renewal of Present Agreement Seen as Probable Program of Union

In Message to Indianapolis Convention Lewis Declares for Contract Running "a Term of Years"—"Reds" in Minority—Union in Sound Financial Condition

(Special Dispatch to Coal Age)

INDIANAPOLIS, Ind., Jan. 22.—A loud radical noise, but not much radical action, is expected out of the biennial convention of the United Mine Workers of America, now in session here. The session, which may run two weeks, gave evidence as it opened today, of framing a union program that will call for a continuance of the present scale and working conditions "for a term of years." It is entirely likely such demands as the five-day week and six-hour day will be put into convention resolutions, as usual, but that the scale committee, when it goes to Jacksonville, Fla., to meet the operators Feb. 11, will forget about them.

The advocates of nationalization and recognition of Soviet Russia were reasonably numerous in the convention as it assembled its 1,500 delegates in old Tomlinson Hall, but they appeared to be decidedly in the minority. Also Alex Howat, of Kansas, who is trying still to fight his way back into the organization after having been booted out for calling a long ago unauthorized strike in the Southwest, is here; but without the strong support of Frank Farrington's full Illinois strength, which backed Howat in vain at the last convention.

Farrington Heads Scale Committee

Frank Farrington was appointed chairman of the scale committee to meet the operators Feb. 11. The remainder of the committee will comprise district presidents and national officers, as usual.

The vast bulk of proposed convention resolutions sent in from district conventions called for a variety of things, but not many of them favored a demand for a marked increase in miners' wages, except one from Ohio, which asked 25 per cent increase. Most of them were said to be aimed to obtain better working time, instead of better pay; however, none of the districts proposed any cures for low market or any of the other factors contributing to short running time.

President John L. Lewis, in his mes-

sage, declared for a contract running "a term of years" in the following words:

"The industry needs breathing spell for purposes of readjustment to present day conditions. The laws of supply and demand have not operated within the industry for a period of six or seven years. A wage agreement for a term of years, effectuated without a strike or suspension of production would be of constructive help in restoring stability to the industry and would indeed be a boon to the coal-weary public.

"Were such an arrangement possible, it would demonstrate to the coal-consuming public that the industry itself was making a sincere attempt to put its house in order. Such a policy, if carried out, would eliminate the necessity for coal legislation by the federal Congress or the various state legislatures. I am not one of those who believe that the enactment of arbitrary legislation will prove a panacea for every maladministration of the industry, or that economic laws can be set aside by the sweep of a legislative pen."

Mr. Lewis pointed out that during 1923 the country produced 545,000,000 tons of soft coal and worked but half time. This indicates the industry has development, investment, equipment, and man-power to produce a billion tons a year. "Such a situation," he said, "is unsound from every moral and economic standpoint, and constitutes a crying need for adjustment." He did not, however, propose any method of adjustment beyond implying that if the present scale is continued for "a term of years," the workings of economic law will remedy both overdevelopment and overmanning of mines. Mines which cannot stand the gaff will fall.

Mr. Lewis made much talk about the strength and unity of the organization, asserting that internal differences had been composed. Reviewing 1922-23 he said the record of victorious achievement of the union is "without parallel in the history of our organization."

Vice-president Philip Murray, in racy language, paid his respects to the Reds within the organization, but declared that "in this country there is too much soap, too many Gillettes and not enough whiskers to accept the bearded philosophy of Russianized revolution." He said the whole coal industry ought to be unionized because there would be very little friction in the industry were it not for them, for there could then be no exploitation of mine labor, no stealing of markets by low-cost coal, and many benefits to the public as well as the mine workers.

Union Finances Improve

Financially the union is in better shape than it was at the outset of the 1922 strike, it appears from the report of Secretary-Treasurer William Green. Whereas the union went into the 1922 strike with only about \$250,000 it now has on hand \$1,177,000. During the 1922 strike \$848,000 was borrowed, \$350,000 from the Indiana National Bank, of Indiana; \$150,000 from the Harriman National Bank, of New York; \$50,000 from the Bank of the United States, another \$50,000 from the Brotherhood of Locomotive Firemen and Enginemen and the rest from Districts 2, 6, 9, 11, 13 and 23 of the United Mine Workers. A total of \$116,000 was given the organization by friendly labor groups. During the two years and four months ending last November income from all sources was \$8,747,000. The heaviest expenditures for union work went out as follows: District 17, \$1,428,000; District 16, \$649,000; Coke Region, \$495,000; District 10, \$442,000.

Indicative of the amount which the union can raise from its own membership, Mr. Green reports that the special assessment of November and December, 1922, of \$2 per month per member brought in about \$1,760,000; the membership figures of the union for recent years show the following: 1920, 376,447; 1921, 442,000; 1922, 285,900; 1923, 445,734.

A REGRETTABLE ERROR was made in the table showing average spot prices of bituminous coal, f.o.b. mines, and the accompanying table showing relative prices of bituminous coal, on p. 110 of last week's issue of *Coal Age*. In the column showing prices for 1922 that for June was given as \$2.56 when it should have been \$3.31, and in the corresponding month and year in the table showing relative prices the figures for June should read 274 instead of 212.

Navy Opens Bids for Steaming Coal

The Bureau of Supplies and Accounts, Navy Department, received the following bids Jan. 20 for supplying 10,000 tons of steaming coal for delivery at New York between the date of contract and June 30 next:

For delivery f.o.b. vessels or barges under chutes at piers: W. H. Bradford & Co., Philadelphia, \$6.26 per ton; Coleman & Co., Philadelphia, \$6.25; Consolidation Coal Co., New York, \$6.57; Dexter-Carpenter Coal Co., New York, \$6.46; Morrisdale Coal Co., Philadelphia, \$5.59; Pattison & Bowns, Inc., New York, \$5.99; Titan Fuel Corporation, New York, \$6.39, and J. H. Weaver & Co., Philadelphia, \$6.06.

For delivery f.o.b. lighters or barges alongside vessels: W. H. Bradford & Co., \$6.49 per ton; Coleman & Co., \$6.45; Consolidation Coal Co., \$6.75; Dexter-Carpenter Coal Co., \$6.81; Morrisdale Coal Co., \$5.83; Titan Fuel Corporation, \$6.63; J. H. Weaver & Co., \$6.30.

For delivery in harbor, in lighters, coal to be unloaded, stowed and trimmed: Coleman & Co., \$7.15 per ton; Dexter-Carpenter Coal Co., \$7.99 and \$8.19; Morrisdale Coal Co., \$6.70; Titan Fuel Corporation, \$7.34; J. H. Weaver & Co., \$7.20.

An informal bid was received from Cosgrove & Co., Johnstown, Pa.

Rice to Tell A.I.M.E. of His Observations in Europe

George S. Rice, chief mining engineer, Bureau of Mines, will report the result of his discussions with foreign technical societies regarding the collection and interchange of data on ground movement and subsidence at the 129th meeting of the American Institute of Mining and Metallurgical Engineers, which begins Feb. 18 in New York City. Mr. Rice's report will be read at the afternoon session of the first day of the meeting.

Howard N. Eavenson, of Pittsburgh, Pa., will preside over the joint session on coal and coke, ground movement and subsidence, which begins in the morning of the first day, and will welcome to the meeting Dr. R. V. Wheeler, director, British Safety-in-Mines Station at Eskmeals, and Henry Walker, Deputy Chief Inspector of Mines. They will reply to Chairman Eavenson, and Dr. Rice, who was in Europe last summer, will give an illustrated talk on the mining methods he observed in Europe during his recent trip and on the methods used in restoring the coal mines in northern France.

At the session devoted to industrial relations on the same day sub-committees will report on safety, employment and industrial organization, education, and the physical and mental factors in industry.

The session devoted to coal will be held on the afternoon of Feb. 19 with Mr. Eavenson presiding. The speakers

Man the Pumps!

A new method of handling peat out of bogs has just been patented in the name of the late Captain Alexander McDougall, of Duluth, Minn. Rotary pumps mounted on scows in the bogs would be expected to pump the peat through flexible piping to a drying plant, the process of which is not described. The pumping process is intended to replace the draining of peat swamps and the cutting of the material by hand or machine.

will include Mr. Eavenson, Ray W. Arms, contracting engineer, Roberts & Schaefer Co., Chicago, and G. B. Southward, chief engineer, West Virginia Coal & Coke Co., Elkins, W. Va.

Charles H. MacDowell will preside at the meeting devoted to timber requirements and reforestation, and at the session on iron and steel and refractories, P. H. Royster, assistant metallurgist, Bureau of Mines, Minneapolis, and T. L. Joseph, assistant metallurgist will present a joint paper on the effect of coke combustibility on stock descent in the blast furnace.

Industrial relations will be discussed at two sessions to be held on Feb. 20, the last day of the meeting, one to be held in the morning under the direction of Arthur L. Notman and the other in the afternoon. Of the latter Sidney Rolle will be chairman.

The annual business session will take place on the morning of Feb. 19, when the election of officers will take place.

During the sessions several committees will hold dinners and the annual banquet will be held at the Waldorf-Astoria at 7:15 p.m., Feb. 20. The following day the members of the society will visit the Bethlehem Steel Works. A program of entertainment has been arranged for those women who accompany the members to the city during the meeting.

Trade Commission Accuses California Dealers

Suppression of competition is charged by the Federal Trade Commission in a complaint against coal dealers allied with the California Retail Dealers' Association, its eight local organizations and thirteen wholesale or producing corporations in the coal business in California and Utah. The complaint charges the companies and persons named with having fixed prices and attempting to shut off the supply of coal to co-operative purchasing enterprises or to non-member retail dealers in the trade.

The hearings scheduled before the Federal Trade Commission Jan. 17 in the matter of the complaint against the Northwestern Coal and Dock Operators' Association have been postponed until the latter part of the month, the commission announced.

Premium Anthracite Sales Continue to Decrease

Reports of wholesale dealers in anthracite for the two weeks ended Dec. 15, covering only premium coal of domestic and pea sizes, show a marked decrease in the proportion on which a gross profit of 50c. or more was obtained, according to the Federal Trade Commission. Continued use of coke, bituminous coal and other substitutes for anthracite, especially for stove and nut sizes, which appear to be in the greatest demand, the commission says, will hasten the elimination of premium anthracite from the market and establish the entire trade on a healthier basis.

Although gross profits ranging up to \$1.75 per ton are still being realized by some wholesalers on a small part of the tonnage handled, and the passing of anthracite through the hands of two or more wholesalers still tends to enhance the prices of a part of the anthracite handled by wholesalers, the main cause of high prices charged the consumer continues to be the premium exacted at the mine by producers of a comparatively small proportion of the total anthracite output.

The wide range in the gross profits reported by wholesalers is gradually disappearing, the report says. During the two weeks ended Dec. 15 gross profits were reported ranging from \$1.75 per ton on anthracite sold at \$12.50 to a loss of \$1.05 per ton on coal sold at \$8.95 per ton f.o.b. mine.

For the two week period ended Dec. 15, 77 per cent of all the reported tonnage of wholesalers of premium anthracite was purchased from the producers and sold to a retailer or consumer, thereby passing through the hands of but one wholesaler; 19 per cent passed through the hands of at least two wholesalers, and 3 per cent through the hands of at least three wholesalers. For domestic sizes sold at premium prices 74 per cent of the tonnage reported passed through the hands of but one wholesaler; 24 per cent through the hands of at least two wholesalers and 1 per cent through the hands of at least three wholesalers.

During the two weeks ending Dec. 15 80 per cent of the carloads of high-prices domestic sizes of anthracite reported as sold by wholesalers was purchased directly from the producer.

Morrow in Loader Business

J. D. A. Morrow, formerly executive vice-president of the National Coal Association and for the last year president of the Morrow Callahan Coal Co. and the John Morrow Coal Co., has just been elected vice-president and general manager of the Joy Machine Co. with headquarters in Pittsburgh. It is understood that the Joy company is about to bring out a new and larger model of its mechanical loader. Mr. Morrow will continue his connection with his coal companies.

Symposium by Scientists in Washington Reflects Growing Interest in Coal

Sovereignty of American People at Stake, Says G. O. Smith—Tryon Cites Illegality of Plans for Birth Control of Mines—Hood's Paper a Feature

An indication of the increased interest in coal was had last week when the Washington Academy of Sciences—a body which rarely considers economic questions—devoted a session to a discussion of that subject.

In opening the discussion, Dr. George Otis Smith, Director of the U. S. Geological Survey, declared that the real issue today "concerns the sovereignty of the American people in their relation to those who own coal mines and to those who work in coal mines." In leading up to that conclusion, Dr. Smith cited as the outstanding cause of the difficulties in the bituminous industry the uncertainty of its labor supply. "The present monopoly of mine labor," he said, "has followed in the trail of the union's necessary, beneficial work in behalf of the mine worker, but that labor monopoly is no less injurious to the general public, and its power needs to be curbed. Each and all of the reforms advocated by the Coal Commission will fail to stabilize the industry if periodic suspensions of mining are to continue. The open threat of tying up the commerce of the nation and shutting down its industries is the menace of economic chaos."

Charles P. Neill, a member of the Harding Coal Commission, called attention to the tendency of unionization to break down the spread between the fixed wages paid skilled and unskilled workers. He cited examples to show that skill adds very materially to earning power among piece workers. He made the statement that the public had no right to anthracite now at the prices paid prior to 1910. The price was not sufficient to allow the men adequate pay for the work they did and the risks they necessarily must run in winning the coal. To hear operators talk, said Mr. Neill, one would judge that all mine workers have an annual wage of \$5,000. When union leaders discuss it, the impression is that no mine worker gets more than \$500 a year. The inequality in wage payments in the coal industry, he declared, is between the man who works 300 days a year and the man who works only 70 days.

In the course of discussing the relation of the cost of production to prices of coal, David L. Wing made the point that relatively few persons realize the wide ranges of costs even in the same field. He explained how coal companies operating side by side and selling in the same market may have such varying costs that the relationship is three to one. If the mines are under separate managements, a wide range of efficiency might exist in the conduct of the property.

The thickness of the seam, its pitch,

the purity of the coal, presence of faults, the drainage and ventilation problems, the amount of timbering necessary, the age of the mine, character of the mining, he said, indicate physical conditions which might cause great differences in cost. One of the mines might lose time because of accidents, because of car shortage or because of labor trouble. Other factors which contribute to differences in costs are royalties, depletion, depreciation charges and officers' salaries.

H. Foster Bain, Director of the Bureau of Mines, discussed the cost in lives of mining coal. The whole trend now, he said, is toward greater mechanization, with its increased hazards, the greatest of which is the more general use of electricity in mines.

F. G. Tryon, coal statistician for the Geological Survey, reviewed the various proposals to check the birth rate among bituminous coal mines and pointed out that not one of these proposals was free from serious doubt as to legality or practicability.

George S. Rice, chief mining engineer of the Bureau of Mines, reviewed the British coal agreement of 1921, pointing out that the present demand for its suspension by labor did not mean repudiation of the principle of profit sharing but is simply a dispute as to the terms of division.

E. W. Parker, of the Anthracite Bureau of Information, admitted that the prices of the domestic sizes of anthracite are too high but he asserted that this is due to the fact that the price of the steam sizes is too low. He said all authorities agree that the small sizes constitute just as valuable a fuel. He believes the public will benefit materially by the educational campaign now being conducted by the anthracite operators in an effort to teach domestic consumers how small sizes may be burned as easily as the coal which they have been accustomed to buy.

A feature of the meeting was a paper on "Consumers' Economies," read by O. P. Hood, chief mechanical engineer of the Bureau of Mines.

"The domestic consumer handles about a sixth of our fuel," said Mr. Hood. "His influence on conserving the general supply cannot be so great as that of the other main users, but his attitude of mind toward coal problems is of great importance and out of proportion to his tonnage interest. He buys the highest priced coal, costing two or three times as much per ton as the industries pay, so that his financial interest is not represented by his tonnage interest. The art of burning coal he must pick up by himself. It is not

No Law Agin It

Two miners working in a mine of the Kaw Valley Mining Co., near LaCygne, Kan., stood on their constitutional rights to smoke in the mine the other day. Both were taken to a hospital. They were carrying a damaged keg of powder when they lighted up.

"You should have known better than to smoke while carrying powder," a deputy mine inspector reminded Clarity, a negro, one of the men.

"But, boss," Clarity replied, "they ain't no law agin smokin' in a mine."

taught with his arithmetic, nor does it go with his athletics. He sometimes makes a sorry mess of it, and at best it is a dirty, dusty and unwelcome job.

"Anthracite has been a nearly fool-proof coal. While it can be misused and give low efficiency, it is surprising how highly efficient it is with the most ordinary care and attention. It is a mistake to consider the average efficiency low. From 60 to 80 per cent of the heat probably gets into the house if one half tries. It is for this reason that it is so hard to displace with substitutes, for each substitute requires the application of a little more thinking and a little more labor, two items we are loath to give.

"In fact, this condition has produced an opposite effect to that of money economy. Instead of reducing the cost of this item of household economy, many are frankly facing an increased item in the budget for the winter's heat and using oil or gas, but requiring a superior type of service that no other fuel supplies. The cleanliness possible with oil or gas makes the basement a totally different place in the home, and allows its use for purposes not thought possible before.

"One of the most practical economies is to use the steam sizes of anthracite, which must sell in competition with bituminous coal. Equally good service can be had if means are provided to maintain a thin and uniform fire bed or to supply artificial draft. The economy adopted by most people will ultimately be the use of bituminous coal. In this district it will be the so-called smokeless coals which we must learn to use.

"They will require more care and attention in firing and a frequent cleaning of furnace heating surfaces. When we are willing to do this in moderate amount the smokeless coal will replace anthracite ton for ton. When we are ready to give really careful attention to the problem we can get along with less tons, for the potential heat is 10 to 15 per cent more per ton. If we are not willing to do more than we do with anthracite at present, we may make up our minds to thoroughly dislike the dirty stuff and let it go at that, which is, of course, quite unreasonable."

Nova Scotia Strike Affects 12,000 Coal Miners

The mines of the Dominion Coal Co., a subsidiary of the British Empire Steel Corporation, are idle once more. The company ordered a 20-per cent reduction in wages on Jan. 15, and the members of the United Mine Workers for the eastern Canada district refused to work under the reduction. While the reduction was to affect only the miners employed in the Cape Breton collieries, many of the miners employed in other sections have refused to work, as a sympathetic move, and it is declared they will not resume work until the trouble in the Cape Breton mines is amicably adjusted. About 12,000 men are affected.

Negotiations for a new wage agreement between the British Empire Steel Corporation and the officials of the district union had been in progress at Sydney, N. S., for several weeks. The miners asked for the rates of 1921, which was refused, the company proposing a 20 per cent reduction. The company on the same day posted notices of a 20-per cent cut in all the mines. Following a mass meeting of the miners a strike of miners at the Thorburn and Stellarton workings on the Nova Scotia mainland fields was ordered.

The company maintains the reduction is necessary and that a lockout was not intended. The provisional executive has ordered all the miners to remain away from the mines until further notice. In the meantime, President Wolvin, of the British Empire Steel Corporation, has sought an interview with President John L. Lewis. Thus far no disturbances have arisen in the strike zone, and no request has been made for troops or provincial police. Government authorities say the maintenance men must be kept in the mines during the strike.

Engineers' Report on Storage Ready About Feb. 1

Dean J. F. Walker of the University of Kansas, chairman of the American Engineering Council's committee on coal storage, announced at a recent meeting of the Executive Board of the council that the report of the committee is in preparation and will be made public about Feb. 1. Dean Walker said that considerable data bearing upon methods and cost of storage, practice in storing and handling of coal, production and transportation, and lost time and overdevelopment in the bituminous-coal producing industry had been collected.

In dealing with the data it has been decided to treat of the conditions in different sections of the country separately. Requirements and the conditions influencing distribution differ so radically in various sections, he said, that no single remedy for existing ills can be devised. Local needs must be fully understood before remedial action

W. P. Jennings

As general superintendent of the Pennsylvania Coal Co. Mr. Jennings is a firm advocate of modern colliery equipment. It was only after a thorough modernization of machinery and processes that the outputs mentioned elsewhere in this issue were made possible.

can be considered. The aim is to give reliable answers to certain questions which those concerned with coal supply will ask when confronted with the problem of adjusting coal demands to a more uniform rate of production.

"There is no specific remedy or cure-all for the coal industry's ills," declared Dean Walker in commenting upon the committee's work. "Anyone who is looking for some act, legislative or executive, which will revolutionize practices and create Utopian conditions, is doomed to disappointment. Certain trends in the economic world have brought about the present situation. Changes will come about gradually in response to adjustments which are in accord with sound business principles, not by creating an artificial superstructure."

VICTOR MURDOCK, chairman of the Federal Trade Commission, has resigned, effective Feb. 1, and will return to his newspaper business in Kansas. His term would not have expired until September, 1925. It is expected that George B. Christian, former secretary to President Harding, will be appointed on the commission.

Ships 21,431 Tons in a Day

The collieries of the Upper District of the Pennsylvania Coal Co., under the supervision of W. P. Jennings, general superintendent, made a wonderful record for a day's tonnage on Dec. 15, 1923, when the district shipped a total of 21,431 tons in one day. No. 1 Colliery shipped 7,557 tons in 170 railroad cars and Underwood Colliery shipped 5,658 tons in 129 railroad cars.

Mt. Jessup Mine Probers Urge Protective Legislation

A recommendation has been made by the anthracite mine inspectors of Lackawanna County that the Pennsylvania Legislature enact a law compelling every coal company or operator in the state to furnish mine inspectors with borehole records to each seam and maps showing the nature and irregularities of the stratum overlying every seam of coal about to be mined.

This recommendation, with others, was made as the result of an investigation into the cause of the accident at the Mount Jessup mine of the Mount Jessup Coal Co., near Jermyn, Pa., on Dec. 8, which resulted in the deaths of five men, including the mine foreman, Eben Jones.

The inspectors, Augustus McDade, L. M. Evans, D. T. Williams and S. J. Phillips, made their report public on Feb. 15 and say that the disaster, like many others, carries with it a lesson that all persons interested in the safe operation of coal mines should learn that too much emphasis cannot be placed on having a thorough knowledge of the strata over all seams of coal that are being mined. Borehole records to each seam and cross-sections of the stratum overlying the seams should show faults, dislocations or discontinuities in the strata, clearly defining and indicating the area of overburden affected and especially the area to be robbed, and no robbing should be permitted except by written permission of the mine inspector. The report says the quantity of coal mined from a central point where dislocations or discontinuities of stratum are shown should be determined in advance of final mining.

In asking that their recommendations be embodied in an act the inspectors say that if a law such as this had been on the statute books many sad tragedies might have been averted and many coal properties that have been practically ruined might be safe and profitable properties at present.

Illinois-Wisconsin Retailers Deny Boycott Charges

The Illinois & Wisconsin Retail Coal Dealers' Association denies charges made by the Federal Trade Commission that it used various methods to enforce an alleged co-operative scheme to boycott so-called "irregular" or "illegitimate" dealers and attempted to have certain producers and wholesalers of coal confine the distribution of fuel in respondents' so-called regular channels. The denial was contained in an answer filed Jan. 21 through Stanley B. Houck, of Minneapolis, attorney for the association.

The association asserts that its acts tend to provide "a higher quality of coal, a more dependable supply, freedom from misrepresentation and fraud in respect to coal, full weight, low prices and generally better coal and better service."

Lewis to Sponsor Coal-Mediation Plan?

Washington Report Is That He Has Scheme to Initiate Public Inquiry Into Labor Conditions in Non-Union Fields—Recalls Hoover Plan of 1919

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Washington is indulging in considerable speculation concerning a report that John L. Lewis is about to present for introduction the draft of a bill providing for some type of mediation in the coal industry. No definite information is available but if the report should be correct, it is assumed that Mr. Lewis has hit upon some plan for the creation of a tribunal to which non-union labor could appeal.

It is hardly to be supposed that Mr. Lewis will recommend a coal labor board, along the lines of the Railway Labor Board, in view of the opposition to that body which has been voiced by the American Federation of Labor and from the fact that the Mine Workers have been accustomed to cite it as a horrible example of what may occur when wage regulation is attempted.

The unions have been so hostile to everything with a savor of wage regulation that it is difficult to believe that they will put forward any suggestion for the setting up of an agency which might be in a position to exercise such control. At the same time there is possibility, it is admitted, that the Mine Workers will be in such straits because of the low rate of employment among union workers as compared with non-union workers that they may be willing to take a surprising step.

Mr. Lewis may have in mind some

such plan as was put forward by Secretary Hoover's industrial conference in 1919. That plan provided the machinery for voluntary arbitration for the country as a whole. There were to be regional boards of adjustment to which either or both parties to a dispute could carry their case. If mediation was sought by either party to the dispute, the regional board would investigate and make a report on the situation even if one party did not agree to the submission of the question to the board. If, under any conditions, the contending parties did not accept the findings of the regional board, it could be carried to a national board—a sort of Supreme Court of industry. There was no thought of compulsion other than that which could be exercised by bringing public opinion to bear.

Such a plan would result in a public inquiry into labor situations in non-union territory. Unquestionably the union would like very much to see it operative there, but if it were operative in the non-union fields it necessarily would have to be set up in the union fields, a thing which they would not like.

What seems more probable is that Mr. Lewis has some plan which will forward his scheme for establishing a minimum wage.

Mines Appropriations Pared From Estimates

The Interior Department appropriation bill for the fiscal year beginning July 1 next, as reported to the House, provides \$1,890,700 for the Bureau of Mines, an increase of \$121,000 over the allowance for the current year but a decrease of \$18,873 from the estimates. Detailed appropriations for next year are as follows:

Investigating mine accidents, \$350,000 (decrease, \$43,000); operating mine-rescue cars, \$262,300 (increase \$51,300); purchase of an additional mine-rescue car, \$40,000; testing fuel, \$138,280 (increase \$2,280); mineral-mining investigations including silver investigations, \$128,360 (increase \$3,360); petroleum and natural-gas investigations, \$500,000 (increase \$95,000); oil, oil shale and gas work, \$91,360 (increase \$11,360); maintenance of mining experiment stations, \$200,000 (increase \$25,000); care of buildings and grounds at Pittsburgh, \$57,400 (increase \$2,400); mining station and mine inspection in Alaska, \$35,000. Payments to the states next year under the leasing act are estimated at \$2,500,000. For the Geological Survey \$1,642,-

760 is provided, a decrease of \$27,430 from the current year and of \$162,512 from the estimates. The detailed appropriations are: Topographic surveys, \$500,000; geologic surveys, \$300,000; chemical and physical researches, \$40,000; report of mineral resources, \$125,000; investigation of mineral resources of Alaska, \$75,000; gaging streams, \$170,000; geologic maps, \$110,000, and classification of lands, \$250,000, the latter being \$30,000 less than the current year.

Urges Federal Mine Operation In "Emergency"

The President is authorized to declare a national emergency in case of cessation or threatened cessation of a steady supply of coal and to take over and operate the coal mines during such emergency by the provisions of a bill—H.R. 5263—introduced in the House by Representative Treadway, of Massachusetts. The measure authorizes payment to operators for the taking over of their property, and appeals from unsatisfactory payments would be made to the Court of Claims. The bill also authorizes the President to fix coal prices during such an emergency.

Oddie Defends Mines Bureau

A recommendation by the Institute for Government Research that the Bureau of Mines be abolished is sharply resented by Senator Oddie, chairman of the Committee on Mines and Mining, who characterizes it as a reflection on the mining industry. The institute's recommendation is made in a report by W. F. Willoughby on proposed reorganization of federal administrative departments. Herbert Hoover, Secretary of Commerce, and Chief Justice Taft are among the members of the institute. In recommending abolition of the Bureau of Mines the institute report says:

"Abolition of the Bureau of Mines is recommended since careful study of its activities shows that there is nothing done by it which cannot be done by other services and particularly by the Bureau of Standards and the Geological Survey. This being so, it is believed to be in the interest of economy and efficiency that it be discontinued and the duties taken over by the other services mentioned."

Notwithstanding this attack Senator Oddie announced that he would press his bill to create a Department of Mines. "Those advocating abolition of the Bureau of Mines do not know the mining industry," declared Senator Oddie. "The mining industry should be dignified by a department of its own." The Senator explained that it would be possible to reduce the number of mine strikes, if not eliminate them entirely, through the continuing activities of a Department of Mines.

Another Anthracite Exhibit In Washington

An exhibit designed to educate the consumers in the proper use of small sizes of anthracite, in order to relieve the demand for domestic sizes and thus tend to reduce prices, has been arranged by the General Policy Committee of the Anthracite Operators at 1328 F Street, N.W., Washington.

The exhibit, located in the heart of the retail business district, contains samples of the various sizes of coal, together with charts and descriptive matter on the walls. Moving pictures of mining operations and of proper methods of firing anthracite are displayed at frequent intervals. Literature on the subject is distributed to callers. The exhibit is similar to the one conducted in Philadelphia.

Borah to Present Pinchot Bill

Senator Pepper, of Pennsylvania, having declined to introduce Governor Pinchot's anthracite bill, the Governor has turned it over to Senator Borah, chairman of the Labor Committee, who will sponsor it in the Senate. Senator Pepper said he did not desire to introduce the measure, as he might not be able to give it his wholehearted support. Mr. Borah is expected to present the bill this week.

Practical Pointers For Electrical And Mechanical Men

Simple Attachment Insures Effective Method of Lubricating Trolley Wheel

Men in charge of mines are always looking for, and eager to take advantage of, any improvement or new device that may be profitably applied to operating machines in and around their mines. Many machines in mining have reached such a point of perfection that continuous operation would obtain but for a defective accessory. The lubricat-

the result of applying lubrications for reducing solid friction to a minimum. Therefore the substitution is a cost reducer and can be made practically complete by efficient lubrication, thereby reducing frictional resistance to the lowest possible minimum on bearing surfaces. If lubrication is deficient either in quantity or quality solid friction becomes excessive and the bearings will be continually roughened by the sliding contact, which creates an ideal condition for increasing frictional losses and quick wearing out of parts. Such deficiencies are not so much the fault of the lubricant as the lack of proper application of the lubricant.

COST ITEM IMPORTANT

Even though a device or improvement may be small the item of cost is ever present in the mine operator's mind, and if comparative costs are in favor of the new device or improvement, he immediately tries and often adopts such an improvement. In the ordinary trolley-wheel frame it is customary to oil the trolley wheel by dashing black oil over the trolley harp, with the result that little of the oil reaches the parts to be lubricated. This is an accessory requiring considerable expense for upkeep, and in addition is at times a source of much trouble in causing delays, and this fact is particularly noticeable on long hauls.

A trolley-wheel frame has recently been evolved which provides for effective lubrication of the rubbing parts. This frame is designed for oiling the trolley wheel and axle with cup grease. The method of lubrication is best understood by referring to the accompanying sketch: The brackets (a) and (b) are the same as those used in the make-up of the ordinary trolley harp. The replaceable brass plate (c) is $\frac{1}{8}$ in. thick and pivoted to the base at the rear by a countersunk-head bolt. The shoulder (d) is hollowed and threaded on the inside full length and has an inside diameter of $\frac{1}{8}$ in. A cap-screw (e) of the same fit ($\frac{1}{8}$ in.) and $\frac{5}{8}$ in. long forces the grease up through a $\frac{1}{8}$ -in. opening into the hollow axle (f), thence through the ports (g) to the outer surface of the axle and inner surface of the hub of the trolley wheel. The axle is made of steel and fixed to avoid rotation by a slotted cotter key at each end, as shown in the sketch. It is esti-

mated that two turns of the cap screw will force enough grease to supply ample lubrication throughout a shift of work.

HOMER COTÉ,
Mining Engineer.

Danger Lurks in Using 2,200-Volt Transformers On 4,000-Volt Lines

No doubt many 4,000-volt lines around the collieries and mines of the country originally were 2,200-volt lines which have been raised to 4,000 volt in order to transmit larger amounts of power to certain districts. When this is done there is frequently a considerable amount of apparatus wound for 2,200 volts which must either be

LUBRICATING ATTACHMENT FOR
TROLLEY WHEEL

By screwing up the cap screw into a chamber which is connected to the wheel spindle the trolley wheel is efficiently greased.

ing system of a trolley-wheel is defective and is a source of loss of time and expensive delays in haulage.

Comparative data from one mine that once used the system of dashing black oil on the trolley-wheel shows that twenty-five bronze graphite bushings were required to wear out one trolley-wheel at a cost of 22c. per bushing. The trolley harp with the grease oiling system was installed on each motor, with the favorable result that only one bushing was needed to wear out one trolley wheel. The trolley wheels were of the same diameter. Many other advantages no doubt have resulted from this installation. This is omitting the inestimable cost of delayed haulage.

In the operation of machinery two kinds of friction have to be overcome: Solid friction, which results from contact of rubbing parts, and fluid friction,

FIG. 1—USUAL CONNECTION FROM
LINE TO GROUND

On a 4,000-volt grounded neutral system the voltage from a line wire to ground is about 2,300, so it is possible to use a 2,200-volt transformer in this way.

FIG. 2.—HOW THE BLACKSMITH WAS SHOCKED

By placing his body in the circuit from the line wire to ground the man received a bad shock. The reason he was not killed was that his contact to ground was not perfect and he did not get the full force of the 2,200-volt pressure.

used on the new line operating at 4,000 volts or be transferred to some other location where it is again used on 2,200 volt-circuits.

Under these conditions lighting transformers built for 2,200-volt circuits may easily be used between one line wire and ground wherever the 4,000-volt line is operated with a grounded neutral.

This, however, introduces liabilities to accidents, one of which happened at a mine near our town. A lighting transformer was connected in the usual way, one side of the primary winding being connected to a line wire and the other side of the primary winding running down the side of the pole to a ground connection.

One day a wagon delivering supplies to the mine grazed the side of this pole, and the hub of the wagon wheel cut the ground wire. Immediately the lighting around the colliery went out, and a small forge fan motor working on the same circuit stopped. The blacksmith went out to see what the trouble was and knowing something about electricity immediately noticed that the ground wire from the transformer was broken off.

He had previously heard the electrician say that touching a ground wire would not harm anyone, and this was very often demonstrated to him, so he saw no reason why he could not make the repair to the ground connection of the transformer without any danger. He therefore touched the up-

per end of the ground wire and soon found himself curled up on the ground. This was quite a surprise to him and it was a fortunate thing that the ground on which he was standing and the shoes which he was wearing prevented him from receiving the full force of the voltage.

Many electricians have a false idea of ground wires and this is one instance where a ground wire was really dangerous, for in effect the blacksmith touched a line wire and got a bad shock because the circuit was complete from the line through the transformer primary to ground.

Another Motor Generator Set Without a Ground Wire

The stories which I have recently read in *Coal Age* referring to motor-generator sets which were not supplied with a ground wire until a serious accident almost occurred prompts me to tell you about an experience along the same lines which I once had.

The machine in question was set up as usual on a concrete floor and when a breakdown occurred in the motor winding the high a.-c. voltage sought various ways to reach ground. Cracks in the floor around the machine, although very small, had been filled up with coal dust from sweepings of the floor and a slight amount of moisture occasionally was noticeable along the cracks.

When this machine broke down the operator had the scare of his life. He closed the starting switch and saw streaks of fire along every crack leading from the motor-generator set, some of these streaks of fire running out from the sides of the machine along the cracks as much as 2 ft.

We took no more chances with there

FIRE CAME OUT OF THE CRACKS

The leakage from the machine was along the cracks, which became luminous when the power was applied to the machine.

not being a good ground on this machine by taking the insulation off the negative stud of the generator and connecting our negative lead to the track return from the mine and a nearby ground located in moist earth. This may be done with most machines and I offer it as a suggestion because ground wires ordinarily put on machines are of rather small diameter and may be burned off or broken and yet not be noticed. There is not much chance of a heavy return wire from the mine being broken and not noticed, because it probably is the only source through which the circuit from the mine is completed back to the negative side of the generator.

ELECTRICAL INSPECTOR.

Electrician Helps Himself By Helping Others

Unfortunately for mine locomotives as well as the power house there is entirely too much parallel operation of the locomotive motors. Strange as it may seem, some motormen go through years of actual operation without really knowing the locomotive with which they work.

The blame for this condition does not lie entirely with the motorman but rather with the electrician in charge, for it is the latter's failure to impart a small portion of the knowledge he possesses concerning certain things having to do with the operation of the locomotive that makes certain details of the equipment forever a mystery to some motormen. It is unfortunate that this condition should exist, but it will persist until electricians in general are more liberal with the knowledge they possess and pass it on to others less fortunate than they in being placed in positions of advantage.

One has only to look back at the time of one's own apprenticeship to appreciate the real force of this statement. Many sad chapters could be written of some motormen, eager for knowledge but afraid to ask for it because of the ridicule of some of their fellows, thus they remain motormen to the end of their days, and all because electricians in general remain blind to the harm they are doing themselves, their company and their fellow-worker in withholding information which would help make the work easier, safer and more efficient. The fact that there is always less trouble with a locomotive operated by a capable motorman is sufficient proof that it pays to have the electrician pass on his knowledge of the intricate parts of a locomotive to the man who runs it. Discussion

Wants Are Due to Erosion

BY GEORGE A. SCHULTZ
Superintendent, Liberty Fuel Co.,
Latuda, Utah.

On p. 783 of the Nov. 22 issue of *Coal Age* Charles E. Lawall, of the University of West Virginia, has an article on what he terms "faults of erosion." The article deals with a subject of great importance to many of the mining companies in Utah and, I have no doubt, in other districts also.

In the Utah coal fields "faults of erosion," as Mr. Lawall terms them, are known as "wants," but I feel sure that neither term should be applied to many of these unusual occurrences. There is no question but that wherever these "wants" extend continuously for a number of miles their origin is easily explained. No doubt they are, as Mr. Lawall states, the result of coal being eroded by a stream, the stream bed in turn being filled with material which eventually forms rock.

I have mapped, however, a number of coalless areas after the coal had been extracted around them and have found that their lack of uniformity in outline always is striking. I have known them to vary in area from one-half acre to forty acres and in outline from the shape of a cigar to that of a side view of a duck. Some of them are separated from each other by 200 ft. of coal and others by about a mile.

Geologists have tried to explain these occurrences by saying that the larger ones are caused by stream erosion and the smaller ones by the eroding action of whirlpools in the stream, but their shapes are so irregular that these theories are unsatisfactory. My experience has been that the roof of the coal usually comes down over these wants, though with varying angles.

Sometimes the coal will gradually become thin from roof to floor, the change taking place in a distance of several hundred feet. On the other hand, in some instances the coal will become thin in a few feet, proving to me beyond a doubt that such wants are not due either to the erosion of the seam or to the formation of islands in the swamp or bog while the coal-forming material grew or was deposited.

One theory that has been advanced seems to me quite feasible. This is that the coal-forming material while still of a mudlike consistency was covered with sand or other material, the distribution of this overburden not being uniform. Wherever the greatest weight of material was deposited it settled, displacing the soft peat. The fact that the coal seam surrounding the "want" usually is thicker than the normal thickness of the seam seems to substantiate this theory. Many impos-

sible causes such as intrusions of volcanic origin have been advanced to explain the formation of these "wants," but I am disposed to believe that in most cases they are the result of an unequal deposition of material and of the extrusion of the almost liquid peat in response to unequal pressure.

United Mine Workers and Reds

For several months the publicity department of the United Mine Workers of America has been giving statements to the Associated Press affirming that they have discovered that all of the murders and disorders which have been charged against the miners' union since the war can be traced to the activities of "Reds," who are not in sympathy with the union and who are only using that organization for their own ends.

As bearing on the above statement I have taken a few facts from a brief of the Alabama Mining Institute submitted to the U. S. Coal Commission.

The United Mine Workers called a strike in Alabama in May, 1920, and in September, 1920, that organization sent Van A. Bittner from the International headquarters to take charge of the strike. He was sent as the direct representative of the national officers, and he is still being used on important assignments by the same organization.

The strike was called off in March, 1921, after both sides had submitted their case to Governor Kilby to arbitrate and he had ruled against the demands of the miners. The Governor handed down his decision March 19, 1921. On March 30, 1921, more than a week after the strike had been lost, Van Bittner made a speech at Blocton, Ala., to union men, most of whom had been refused re-employment. The speech was taken down in shorthand by a court reporter and the transcript from his notes sworn to.

Here are a few extracts:

"There has not been any strike yet. We are just going to start. We are going to hold this Governor and these coal operators responsible for that decision. They thought that because the decision was as rotten as it was, as ungodly as it was, the mine workers' union would say, 'Well, we are not going to comply with that decision.'

"It is going to make them fight. That is what it is going to do. If there are any scabs left here in Blocton in thirty days from now, you men ought to be chased out of the state. That is the thing for you to do."

"They may have a right to work, but by the eternal gods, they haven't any right to your jobs. It has been entirely too healthy for scabs around Blocton. That has been the trouble

Wide World Photos

Bathhouse at a Dutch Mine

The roof decorations are, of course, suspended clothes. Apparently four men are employed in keeping the floor clean. Seats are not provided as in American bathhouses. The clothes are suspended by chains and locked in place, each man carrying his own key.

with you. What would you do with a rattlesnake if one of them would start crawling into this meeting now?

A Voice: "Kill him."

Mr. Bittner: "A rattlesnake never did you half as much harm as a scab."

"If they had ever started to drive the organizers out of Alabama there are a lot of coal operators who would never have lived to read about it in the newspapers the next morning. We would have got a few of them in the fight. We are going to stay here just as long as you want us to stay. I think there are enough good, strong, union men to make the weak fellows fight whether they want to or not. I think we have reached that stage here in Blocton and everywhere else."

"We want you to make the mines 100 per cent union. We are going to give you until March 13, 1922, to do this. If you don't do it, we are going to build a fence around this infernal state and let you fellows down here scab and live in slavery all the rest of your days."

Were those remarks inflammatory? What is a "Red" anyway?

Birmingham, Ala. H. S. GEISMER.

Speaking of Queer Names

A small mine located at the junction of the Black and Little Warrior rivers, in the northwestern part of Jefferson County near the Walker County line in Alabama, is known as "Toadvine," which is the name of the small village that was there long before the mine was opened.

A mine known as "Who'd 'A' Thought It" is even more distinguished as a leader in the list of coal mines with queer names. This mine is northwest of Wylam, Ala., and located near Dolomite in Jefferson County. If any one can beat these two names, let him come forward.

P. W. GOOCH,
Superintendent, Coal River Collieries,
Prestonsburg, Ky.

Production And the Market

Strike Rumors and Drop in Temperature Cause Upward Swing in Soft-Coal Sales

Sales in the soft-coal industry, as in some other fields, are showing an upward tendency, possibly owing partly to the prospect of a suspension of work in April. Those having small stocks seem to be anxious. However, the weather in most sections of the country has not been without result. Consumers are showing more interest, inquiries have increased and the sales in January have exceeded those made in December. Some operators report sufficient business ahead to keep their mines going during the month and well into February. The possibility of a strike in England and the railroad dispute are matters much discussed, but so far they have had no general effect on the market. There has been more inquiry regarding contracts. The anthracite situation shows practically no change.

Though spot quotations for soft coal show slight changes in various districts the general result indicates comparatively little shifting from last week. *Coal Age* Index as of Jan. 21 registers the same as it did last week, 182, but the average price is \$2.25, an increase of 5c.

Markets Active in Middle West

The Midwest markets are reasonably active and dealers are kept busy. Moreover, the railroads have been slow to make deliveries, thus preventing an excess of coal from arriving. With the exception of smokeless coals, however, prices remain firm. Business at St. Louis is on the upgrade, the demand for bituminous coal and coke being fair, though slow for anthracite and smokeless coals. Western Kentucky prepared coals are moving better, including a fair tonnage to Chicago. Smokeless coals are not in good demand in the Northwest, but dealers at Milwaukee are having some good business because of the real winter temperatures.

A marked improvement for domestic coals is noted in the Ohio markets. Buying at Columbus is general

and dealers are placing more orders. Distress coal is practically cleaned up and a much better tone has developed. Steam coals are in much steadier demand and generally there is less shading of prices to force sales. At Cincinnati the demand for domestic coals is strong. Retail dealers whose stocks have been depleted are calling for prompt shipments. Retail demand at Cleveland is showing more activity, though operators and jobbers say that the demand from the steel mills is very quiet. Other industrial plants continue to buy for current needs. Steadiness is noted in the Pittsburgh market with a moderate demand for domestic coals. There is a feeling that there will be a suspension of mining on April 1. Demand for steam coal in New England is unchanged from last week; textiles are at low ebb. Trade along the Atlantic seaboard for domestic consumption is quiet, but there is a fair volume of spot coal moving, while at Baltimore interest centers in the export situation.

Soft-coal production during the second week of 1924 is estimated by the Geological Survey to have been 11,921,000 net tons, an increase of 2,853,000 tons when compared with the previous week. This also was the largest weekly output since December, 1920. Output of hard coal for the same week totalled 1,840,000 net tons, as compared with 1,436,000 tons the previous week.

Production of beehive coke during the week ended Jan. 12 was 248,000 net tons, as compared with 236,000 tons in the previous week and 323,000 tons in the corresponding week of last year.

Midwest Prices Firm

Continued cold has kept the Midwest markets reasonably active during the past week. There has been just enough slowness of railroad movement to check a too rapid flow of coal to market, with the result that prices all around have held firm. There have been few increases, however, except a slight upward tendency on the part of smokeless

coals from a field which is already partly shut down. Smokeless lump and egg pushed up to about \$3.50 and mine-run was strong at \$2.25, running up to \$2.50 in some cases. One or two instances of premiums were reported.

An effort on the part of western Kentucky to advance lump prices a little was not greeted with much encouragement. Quotations for delivery up to May 15 from that field at favorable prices indicate that the field does not hope for a sudden rise in the market even if there is a strike April 1, but what would happen after May 15 or thereabouts might be a different story.

Throughout the Illinois and Indiana fields domestic demand has been sufficient to reopen a number of mines that have not worked lately, and has generally improved conditions. Central Illinois, for instance, has been able to sell about all its domestic sizes at \$3@3.25 and screenings have not dragged heavily at \$1.50@1.60. Domestic production in southern Illinois and in the Standard district, however, has been heavy enough to slow down the steam sizes. The Standard field's production is great enough to cause a good deal of backing up of coal there. The Mt. Olive field as

well as the DuQuoin and Jackson Country regions have all been doing fairly good business.

St. Louis Trade on Upgrade

Cold weather has put the St. Louis coal business on the upgrade and the dealers report that demand is fairly good and all yards are active, principally with middle and cheaper grade coals. Coke has shown considerable improvement in the past week, while anthracite and smokeless lag. Franklin County is not selling as readily as the cheaper grades.

Wagonload steam is good, but carload steam is easing off on everything. Business conditions are not as good as they might be and there seems to be an overproduction that is forcing the market. Country steam is active in spots for nut sizes only, while country domestic continues good for the cheaper grades. There has been no change in local retail prices.

Operators in the western Kentucky field have found demand for prepared sizes somewhat better since cold weather created better movement to the Southern markets along

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

Index	1924				1923
	Jan. 21	Jan. 14	Jan. 7	Jan. 22	
Weighted average price	\$2.25	\$2.20	\$2.20	\$4.43	

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

with the Central and Western districts. A fair tonnage has been moving into the Chicago district and to Michigan. Screenings are in larger production, but are being moved fairly well and prices are holding. Prepared sizes are firmer, and not much price cutting is reported.

Car supply continues quite good in all fields of the state, but loadings are heavier and cars on long hauls are not making as good time as they were, but there is less coal standing unsold on cars than for some time past, which helps the situation a little.

Movement of prepared sizes from the mines from both ends of Kentucky is improving, and while screenings are in larger production, there are more consumers in the market, with the result that prices are holding firmly, in spite of some talk of \$1.10@ \$1.15 offerings, made largely by brokers in an effort to break down the market. As a matter of fact it is impossible to trace any screenings moving at under \$1.25 to the consumer; good stock sells as high as \$1.60.

Northwest Trade Quiets Down

Smokeless coals dropped off during the past week, due to the anxiety of dock men to encourage householders to use them as substitutes for hard coal. Prices are as follows for those coals which have changed price: Kentucky

lump, \$7.25; run of pile, \$6.50; screenings, \$4.25; splint lump, \$6.75; run of pile, \$5.75; screenings, \$4; Pocahontas lump, \$9; run of pile, \$6.50; screenings, \$5.50. Screenings are strong all along the line. All other coals are firm.

The spurt in buying so evident the first part of the month was lost last week. Everyone is still buying from hand to mouth. Stocks of bituminous on docks are now estimated at 5,000,000 tons, and unless a strike occurs an oversupply on the opening of navigation is likely. It looks as if at least 3,000,000 tons will be on the docks at the opening of navigation. If there is no strike a reduction is certain.

The anthracite market is a puzzle. No accurate estimate of stocks is available, but it seems certain that not more than 150,000 tons can be on the Head-of-the-Lakes docks, and this mostly off sizes. A small amount of stove and nut remains in hiding, and the docks are delivering one ton of either stove or nut, but the buyer must also take an equal amount of egg or pea.

Real winter weather keeps the Milwaukee coal market lively, and everybody is busy. There is a good supply of everything in the way of coal, but jobbers report a tightening in the supply of Western screenings. Prices of coal and coke remain unchanged.

Western Markets Busy

There is considerable activity in coal trading throughout nearly every section in the West. In Utah some of the mines are working full six-day weeks for the first time in months though the average is still about 4½ days. Domestic call is steady and industrial demand is strong enough to firm up the price of slack a little. The quotations are \$1.25 for straight slack and \$1.75 for screened steam coal. In Colorado the market continues to rise slowly, so that there is only a little time lost nowadays because of "no market." Real winter weather spreads over the entire West.

With mines throughout the Southwestern district working full time as a result of continued cold weather and strong demand, the prices of Kansas nut and screenings were advanced 25c. Jan. 14.

Ohio Markets Show Improvement

With colder weather prevailing there has been a marked improvement in the demand for domestic coals in the Ohio markets. While buying is not as active at Columbus as in some former corresponding periods, orders from dealers are much better and distress coal has been cleaned up. The bulk of the demand is for the better grades of Kentucky and West Virginia coals although there is a good demand for Ohio mined coals. Retail quotations are stronger at some points and there is no inclination on the part of dealers to make concessions. There is more steadiness showing in demand for steam coals. While reserves are large there is a tendency to guard against a suspension and railroads are coming into the market for storage purposes. There is also good buying by the utilities, while iron and steel plants are buying a fair tonnage.

The Cincinnati market is feeling the effects of cold weather and there is a good demand for domestic coals. Quotations for these coals show an upward movement while the lower grades of slack and screenings have been softening. Reports at Cincinnati are that trouble is brewing in the New River district because of the attempt to cut wages. A cut in wages to the 1917 scale is reported from some parts of Kentucky. Dealers are calling for prompt shipments. The retail situation is slightly stronger. Advertised coals are quoted on a range of \$3 to \$4 for lump, \$2.50@ \$3.25 for egg, and \$1.75@ \$2.25 for mine-run.

The only noticeable change in the Cleveland market from last week is that prices on slack have eased off 5c. to 10c. per ton and demand from retail dealers is showing greater activity. Retail dealers have been busy since the first of the year and are replenishing their stocks. With transportation in good condition there is no anxiety among steam-coal users.

Weather conditions have so far failed to help the Pittsburgh market. There is a moderate demand for domestic coal from the mines, but nothing like the normal for the

first month of the year. Industrial operations have increased somewhat. In all business circles in Pittsburgh it is considered a foregone conclusion that there will be a suspension, the only question being its duration. Production in the Pittsburgh district has been running somewhat heavier since Jan. 1, but by no means more than enough to make up for the very light production during Christmas week. In the central Pennsylvania district car loadings amounted to 15,558 cars during the week ended Jan. 12, as compared with 12,878 cars in the previous week. During the same week there were 373 mines idle. The Buffalo trade is not hopeful.

New England Continues Dull

In New England the market for steam coals continues its December status. There is no appreciable change in prices, although tonnages available for shipment diminish steadily as mining is curtailed. The textile industry in general seems to be at low ebb, even though in certain special lines goods are being made in fair volume. Shoe manufacturers have much to contend with, the tire industry is dull, and in fact most industries in this territory have no prospect sufficiently good to warrant larger reserves of coal than are now carried. Among operators there is a feeling that the drastic restriction of output will gradually make itself felt, although the trade realizes it will take a reasonably long period under present conditions to make any substantial gain in prices.

At Hampton Roads there are several agencies with practically no coal at the piers, but even with minimum receipts at the piers there is no advance on No. 1 Navy standard coals as compared with a week ago. About the utmost figure that spot coal will command is \$4.75 per gross ton f.o.b. vessel, and at Boston for delivery inland there are no comprehensive sales at anything above \$6 on cars. The latter is an upset quotation and is realized only now and then as scattering inquiry develops.

For Pennsylvania coals buyers here are as scarce as hen's teeth. Selling agents are given no encouragement, and not even the lowest range of price is attractive. High volatiles of good repute have been offered at as low as \$1.50 per net ton at the mines, but transportation charges are all against them in this section. Steamers at low rates get practically all the cargoes that are dumped at any of the piers and while there is a surplus of this kind of tonnage it is unlikely that the fleets of barges owned by railroad companies will share the traffic to any considerable extent. A few seasonal arrangements doubtless are being renewed, as in the case of railroads, but probably only on a month-to-month basis, and a close canvass of the whole situation discloses no developments of any significance in the Northeastern section.

Increased Inquiries Along Seaboard

Some increase in inquiries was noted in the New York market and indications are brighter, but there has been practically no change in quotations. Buying is ordinary and there are no indications at either New York or Philadelphia that buyers are inclined to assume any different attitude. Consumers are not disposed to discuss any possible labor trouble. There is comparatively little contracting going on,

neither operators nor consumers showing any decided disposition to tie themselves up for any period. At Baltimore the trade's interest is principally centered in the export demand. January so far has been a disappointment to both shippers and producers. Demand has not increased and quotations continue at low figures.

Notices have been posted at some fifteen mines in the New River district in West Virginia that these mines will be shut down until such time as market conditions improve sufficiently to justify their reopening. Larger shipments have been made from the Pocahontas fields to the Western market because of the colder weather. There is a better demand for the prepared coals as well as mine-run. The market at Birmingham continues draggy and unsatisfactory. There is a slight demand for commercial coals in the spot trade, but the orders are small. The domestic situation looks somewhat better due to weather conditions, which have enabled retail dealers to reduce stocks materially.

Quiet Prevails in Anthracite Market

The anthracite trade remains quiet. Demand for egg and pea coals is not lively, while stove and chestnut are in good call in both New York and Philadelphia markets. Most retail dealers are fairly well stocked with all sizes and independent producers in some instances find it difficult to dispose of their coals at more than company prices. In some instances straight lots of stove and chestnut coals bring slight premiums over company price lists. Steam coals are in fair condition, with barley in best demand. Baltimore dealers are kept fairly busy but some dealers are advertising for business. Most dealers hesitate to put in too heavy supplies as they do not want to be caught with heavy stocks on hand should there be a reduction in mine prices this spring. Sufficient anthracite is being received by the Toronto trade to keep them busy.

Judge Says Kansas Mines Are Hard Put

Incidental to recent charges that retail coal prices in Kansas towns were too high, Judge John H. Crawford, of the Industrial Court, on Jan. 16 issued a statement of operating conditions in Kansas, based on a survey made in 1923 by the Industrial Court, a special representative of the Governor and an official of the U. S. Coal Commission, and on information which subsequently came to him. Southwestern operators say Judge Crawford's statement is a true picture of their predicament.

"Unless the cost of production can be lowered in Kansas, and a freight-rate adjustment be effected as favorable to Missouri River points as that granted Illinois, few Kansas and Oklahoma coal mines will be in operation in two years," he declared.

Lake head coal, seeking a market as winter closes its normal outlet, and that produced by non-union mines of southeastern Kentucky and West Virginia, force Illinois to seek a western market, Judge Crawford said. "With a preferential rate to Missouri River points, Franklin County (Ill.) lump coal is sold delivered in the two Kansas cities f.o.b. 50c. a ton less than Kansas coal. This condition has practically driven Kansas coal from Missouri River points.

"There was a time when the railroads took practically 80 per cent of the coal produced in the Pittsburg field. However, this is the day of fuel oil and electricity. The Santa Fe is using oil almost entirely."

Foreign Market And Export News

British Coals in Better Demand; Production Rebounds

Demand for British coals increased greatly during the last few days of the rail wage negotiations. Inquiries were more numerous both for domestic purposes and from the Continent. There has been considerable booking reported in anticipation of the miners' strike, as well as speeding up of deliveries previous to the railway men quitting their places on Jan. 19.

The South Wales markets show much improvement. Orders have increased, but prices show comparatively little change from the previous week. Demand for Newcastle coals is heavier.

The output of the British mines was 4,475,000 tons during the week ended Jan. 5 as compared with 3,383,000 tons the previous week and 5,886,000 tons during the week ended Dec. 22.

Tyne ports bunkering dues have been reduced to pre-war levels as of Jan. 1, making them the cheapest bunkering ports in Great Britain.

The Welsh coal market opened the new year slowly. Just before Christmas there was a rush of orders and the greater part of these have been filled. The output declined so that in many instances delivery was held over until it increased. It is expected that the miners' decision to end the wages agreement will embarrass the trade.

The German State Railways are negotiating for tonnages ranging to about 150,000 tons, contracts for 40,000 tons having been placed. The Norwegian State Railways are in the market for 40,000 tons of steam coal.

Demand at Hampton Roads Dull

Dullness again featured the market at Hampton Roads last week with lack of demand reported from all sides of the trade. The supply of coal on hand dwindled, but there was no scarcity because of the lack of orders.

Coastwise trade was slumping and bunkers held their own. Practically no new foreign business was being reported. Some coal moved overseas on

old contracts. Inquiries dropped off, and shippers continued to make little effort to get business at the present prices.

Conditions on the Virginian Ry. have about reached normal, though the supply of coal for movement to tidewater was reduced. The tone of the market was weak and the outlook not promising.

French Coal Production

Demand for the French industrial and domestic coals eased off early in the new year. The Nord and Pas-de-Calais collieries have increased their prices for the various grades of coal effective Jan. 1, according to the following schedule: Fat coals—raw smalls, 4 fr.; screened coals, 6 fr.; and 5 fr. on other screened coals. Dry coals—raw smalls, 7 fr.; washed peas, 8 fr.; other grades, 4 to 5 fr. Coke, metallurgical, 10 fr.; foundry, 5 fr.; and semi-bituminous and quarter-bituminous coals, 5 to 10 fr.

The high rates for British coals are preventing increased sales, but a decline is expected during January.

During November production of coal from French mines amounted to 3,432,000 tons as compared with 3,609,878 tons, while there were 182,974 tons of coke manufactured as against 190,223 tons in the previous month. Production in the Nord and Pas-de-Calais mines during November was 1,965,771 tons of coal and 129,222 tons of coke as compared with 2,024,097 tons of coal and 131,126 tons of coke in October.

Coal and Coke Exports From Baltimore

During 1923 1,459,482 tons of coal was dumped at Baltimore for shipment to foreign countries, as compared with 101,323 tons in the previous year and surpassing 1921 by 8,339 tons. Welsh coal to the amount of 14,620 tons was received at the port during the year while during the previous twelve months receipts were 113,184 tons. The export

tation of coke from Baltimore during the year ended Dec. 31 amounted to 178,361 tons, while during the previous twelve months no coke was sent abroad. The four nations leading in the purchase of coke during the year were Belgium, France, Chile, and Germany, other shipments going to Cuba, Costa Rica, Italy, Porto Rico and Venezuela. Coal was sent to twenty-four countries, France leading with 463,584 tons of cargo coal, followed by Italy with 316,321 tons to her credit, and Germany third on the list, having received 196,358 tons. During the year twenty-one vessels left for Canada carrying 114,108 tons of coal.

Traffic News

Aver New England Rates Hamper West Virginia Fields

In connection with the hearings before the Interstate Commerce Commission on the petition to lower freight rates on bituminous coal to New England, the point was stressed by attorneys representing the West Virginia operators that if the Winding Gulf and New River fields were to get a rate on a basis similar to that for anthracite, coal production in those fields would be increased 15 to 20 per cent. It is asserted by representatives of the southern West Virginia operators that the rates to New England are unfair and prohibit competition with anthracite on an equal basis. It is pointed out by the southern West Virginia operators that the rates to Chicago or an equal distance west from West Virginia are in some instances one dollar per ton less than the rate for an equal distance to the East.

Joint Hard-Coal Rate Hearing On in Minneapolis

The first hearing in the opposition to withdrawing the joint rate on hard coal from Buffalo to the Twin Cities opened Jan. 17 in Minneapolis. The opposition is headed by the Twin City Coal Exchange, composed of independent dealers, who see in the move a step toward forcing them to buy from the docks and probably to pay more money for dock coal. County Attorney Olson, of Minneapolis, also is participating in the hearing. He has recently conducted an investigation of the coal situation which involved some phases of the dock trade and the independents. He threatens to institute prosecutions if there appears to be any ground for such action, and he has hinted that he believes there is ample ground.

New England Asks Lower Rates

Speakers representing New England urged the Interstate Commerce Commission on Jan. 14 to require railroads to make lower joint rates on coal from West Virginia to New England cities in order to give New England consumers a substitute for anthracite. Edward A. Goss, appearing for Governor Templeton of Connecticut, said the West Virginia coals of the low-volatile type were adequate substitutes for anthracite and with a reasonable rail rate would be taken in quantities throughout New England.

At Odds on Differential

Utah and Wyoming operators were in conflict before Examiner M. A. Patison of the Interstate Commerce Com-

mission at Salt Lake City last week over the differential of 50c. allowed the Wyoming operators some time ago over their Utah competitors. The Utah companies declared the differential of 50c. was unjustified, and asked that it be reduced to 25c. Wyoming asks 90c. Attorneys for the Utah operators said fundamental conditions will always close Eastern markets to Utah coal but that the Wyoming fields are adjacent to the large Middle West market and can profit by it. It was contended that the 50c. differential favors Wyoming in competing for the Pacific Northwest market, a market naturally belonging to Utah. Briefs must be filed by Feb. 29.

12 Per Cent Gain on L. & N.

J. J. Elder, assistant to Wible L. Mapother, president of the Louisville & Nashville R.R., in a recent statement said that the road in 1923 carried 12 per cent more tonnage than in the preceding year.

Industrial Notes

Orders received by the General Electric Co., for the year ending Dec. 31, 1923, amounted to \$304,199,746, compared to a total of \$242,739,527 for the year 1922, or a gain of 25 per cent, according to a recent announcement by Gerard Swope, president of the company. For the fourth quarter of 1923 orders totalled \$74,452,442, as compared with a total of \$66,568,333 for the corresponding quarter in the year 1922, or a gain of 12 per cent. Coal Age estimates that during 1923 the coal industry expended \$74,610,000 for electrical machinery, equipment and supplies.

An important precedent in the granting of patents was established in the District of Columbia Court of Appeals recently when the Court ruled that inventions that have been developed to practical, workable condition should be given preference in the Patent Office over devices involving similar ideas but that have not been so perfected as to be ready for use. Joseph F. Joy, of the Joy Machine Co., Pittsburgh, obtained a patent on his loading machine in 1916, but E. C. Morgan alleged interference, and the Commissioner of Patents held that he was entitled to the patent on a prior claim, as he had applied for a patent on a similar machine in 1910. Witnesses testified, however, that the Joy machine is in practical use by a number of coal companies, whereas Mr. Morgan filed papers on the idea before it had been fully developed. In rendering a decision in favor of Mr. Joy the court said: "This court has commended the course of those who refuse to rush to the Patent Office before the merits of their inventions have been tested. Morgan filed as soon as he conceived the invention, while Joy waited until he was certain that he had a device that would satisfy the demands of the coal mining industry and advance the public interest. We think his course should be approved, and feel constrained to reverse the Commissioner of Patents."

The Automatic Mine Door Co. of Beckley, W. Va., has been organized with a capital of \$200,000, and the following officers have been elected: Dr. W. W. Hume, president; W. T. Ferguson, vice president; W. C. Canterberry, president; S. C. Ballengee, treasurer and manager. This company will manufacture and sell automatic mine doors and is erecting a factory building of frame and sheet iron at Beckley Junction. The new door was patented by W.

W. Ferguson and has been given a number of trials at the Amigo mine, in the Winding Gulf region. All machinery and door castings necessary to begin construction work have been ordered and will be ready for delivery as soon as the building is ready for occupancy.

Association Activities

The Monongahela Coal Association, composed of operators having mines along the Monongahela Ry. between Pittsburgh and Fairmont, held its annual meeting at Pittsburgh, Jan. 17, discussing members' problems confronting the industry in general and particularly those on the Monongahela River and transacted routine business. Officers were elected as follows: Samuel Purselove, of Cleveland, president; R. M. Davis, vice-president, and J. B. Hanford, treasurer. On the board of directors elected in addition to the above officers are: E. F. Miller, George S. Connell, W. R. Mither, B. M. Chaplin, W. E. Watson, Samuel D. Brady, James H. McGrew, E. H. Gilbert, Whitney Warren, W. H. Soper and Stephen Arkwright. The directors at a meeting to be held later will select a secretary.

At the regular meeting of the Columbus Coal Exchange held Jan. 9 it was voted to change the weekly meetings from Wednesdays to Mondays in order to accommodate a larger proportion of the membership.

The Michigan-Ohio-Indiana Coal Association, of which B. F. Nigh is secretary and H. A. Bauknecht, of Muskegon, Mich., is president, has abandoned its usual mid-winter directors' meetings and there are no immediate meetings planned, according to the secretary. The time and place for the annual convention will be taken up by correspondence shortly after the winter season is over. According to Mr. Nigh the collection bureau has been unusually busy during the winter months and many thousands of dollars in claims against railroads have been collected for its members.

Obituary

David Hammond Parker, superintendent of the Clarkson Coal Co., died of heart failure at his home in Wheeling, W. Va., Jan. 16. He was 44 years old. A native of Carlisle, Pa., Mr. Clarkson began his mining experience as a civil engineer. He was for a time connected with the Pittsburgh-Buffalo Coal Co. and also with the Hilton Coal & Coke Co. His wife and two children survive him.

W. W. Harmon, aged 62, a widely known coal man of southern West Virginia and southwest Virginia, died at Tazewell, Va., Jan. 15, after an illness lasting only a few hours. In addition to being extensively interested in coal lands and in active mining properties in southwest Virginia and in southern West Virginia he also was a director of the Bank of Clinch Valley and of the Bluefield National Bank and was extensively interested in stock raising. His wife and two sons, C. Henry Harmon and Sayers Harmon, survive.

William M. Brinker, of Wilkinsburg, Pa., formerly a well-known coal operator, died in St. Petersburg, Fla., Jan. 15, at the age of 80 years.

William T. Grier, former New Jersey State Fuel Administrator and one-time freight traffic manager for the Lehigh Valley Railroad Co., died Jan. 16. He lived at Plainfield, N. J.

Coming Meetings

Rocky Mountain Coal Mining Institute, Winter meeting, Feb. 13-15, Albany Hotel, Denver, Colo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

New England Coal Dealers' Association. Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

American Institute of Mining and Metallurgical Engineers. Annual meeting Feb. 18-21, 29 West 39th Street, New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

Northern West Virginia Coal Operators Association. Annual meeting Feb. 12, Fairmont, W. Va. Secretary, J. O. Caldwell, Fairmont, W. Va.

News Items From Field and Trade

ALABAMA

Negotiations are said to be under way for the consolidation of the Alabama Company and the properties of the Bush interests, large producers of commercial coal and coke. The Alabama Company has extensive ore and coal properties, operating coal mines at Mary Lee, Jefferson County, and at Searles and Brookwood, Tuscaloosa County, with large batteries of coke ovens at the latter two points, and also operates several furnaces in the Gadsden district. The Bush and Hammond interests are owners of the Alabama By-Product Corporation, large producers of coke and by-products and have several active coal mines in Jefferson County, besides being pipe manufacturers. The Hammond-Byrd Iron Co. conducts a large sales agency in Birmingham for the distribution of pipe, coal, coke, iron and coke byproducts. The amalgamation, if it is brought about, probably will involve a capitalization of \$12,000,000 to \$15,000,000.

Warren, Knight & Davis, architects, have been designated to prepare plans and specifications for the **Erskine Ramsay Engineering Hall**, to be erected on the campus of the Alabama Polytechnic Institute, at Auburn. Mr. Ramsay, widely known mining engineer, coal operator and capitalist, contributed \$100,000 in initiating the movement to erect the hall, which is to cost about \$250,000 and is expected to be ready for occupancy for the fall term of 1924.

The Manchester Coal Co., of Manchester, Walker County, will construct about twenty new houses for its employees and also add a new steam shovel to its stripping equipment at an early date. The Jefferson seam of coal is being mined by the stripping process, two shovels now being in use. John M. Kilgore, of Jasper, and associates are developing the property.

CALIFORNIA

A group of Oakland men have opened a mine in the Mendocino field with the expectation of successfully selling domestic sizes in competition with every other coal that reaches the San Francisco district because their product will enjoy a \$4 advantage over the nearest other coal, and they expect it to produce coke for the southern California steel industry. A mine has been opened in Mendocino County on the new extension of the Northwestern Pacific R.R., which runs from San Francisco to Eureka.

ILLINOIS

The Kolb Coal Co. receivership has been lifted. On Jan. 12 the U. S. Circuit Court of Appeals at Chicago issued an order ousting Edwin J. Schubkegel, the receiver appointed nearly two months ago upon the petition of P. H. Sauter, of St. Louis, Mo., who alleged that as a stockholder he had not received his share of the company's earnings. The Kolb Coal Co. operates mines in St. Clair County.

Figures compiled by Scotts Coal Bureau will show that 50 per cent of the coal mined in Illinois in 1923 was mined at a loss, on account of the high overhead and wage scales and poor market conditions.

Joseph Hartley, of Du Quoin has been elected to fill the vacancy of William Hutton as member of the executive board of the United Mine Workers. Hutton is now acting as commissioner for the Illinois Coal Operators' Association.

Robert M. Medill, former director of the state Department of Mines and Minerals of Illinois, has been appointed as receiver for the **Dodds Coal Co.**, at Carriers Mills. The company recently failed to pay its employees the regular semi-monthly payroll. The company is incorporated at \$90,000 and is said to owe \$50,000 in debts.

The Mitchell & Dillon Coal Co. of Chicago is celebrating its golden anniversary this year. In 1874 the concern was organized by Abe Mitchell at Burlington, Iowa. Shortly afterward the company moved to Chicago.

The mine at Braidwood has been idle for some time on account of being flooded, supposedly from seepage from a nearby stream where the workings are 65 ft. below the surface. The water came in during the night and drowned the mules. It is an old mine and pretty well worked out.

The Bartels Coal Co. of Carlinville, will be reopened. The mine is now being cleaned and rehabilitated, preparatory to hoisting coal. The mine is conducted on the co-operative plan and consumption is largely local.

A suit to foreclose a mortgage on the **West Bethalto Coal Co.'s** mine has been filed in the Circuit Court at Alton, because, it is alleged, of failure to pay interest on the mortgage. The mine is working steadily.

Work has been resumed at the St. Clair Coal Co. mine near Belleville, after a shut down which started Nov. 1 last. The "Radium" mine, also located near Belleville, which was flooded Dec. 6 when a hole was cut through into the workings of an abandoned mine nearby and in which several employees lost their lives, also has been reopened. Only a portion of the mine is being worked until the water can be pumped from all the working places.

Approximately half a million tons of coal will be stored in the next two months by the **Missouri Pacific R.R.** near Gorham, in Jackson County, on 100 acres of land leased for the purpose. This is being done in anticipation of a miners' strike in the spring. The coal probably will be shipped from mines on the company's line in Jackson or Williamson county.

Water has flooded the mine of the **Lebanon Coal Co.** at Lebanon. It is thought to have seeped in through quicksand. The mine was re-opened only a few weeks ago after being shut down for some time. It was taken over by a number of the miners employed and was operated as a co-operative company.

Two important mines reopened this month are No. 8 of the **O'Gara Coal Co.** at Eldorado, and No. 2 of the **Wasson Coal Co.** at Carrier Mills.

The Taylor Springs mine of the Indiana and Illinois Coal Corporation, which has been idle two months, has recently been inspected by Hillsboro and outside capital with a view of buying it.

KENTUCKY

James D. Rash, of the St. Bernard Mining Co. interests, Madisonville, Ky., as State Senator from that district, has been appointed on the Senate Rules Committee.

W. F. Bradshaw, coal operator of Paducah, interested in mines in western Kentucky, as well as being a banker, insurance agent and capitalist, has just been elected president of the First National Bank of that city.

The Kentucky Legislature has spent ten days in argument relative to committees, etc., and in getting ready for its session, but so far hasn't passed any bills, or really gotten down to business. This further indicates that a legislative meeting every four years, instead of every two years, as is demanded by some interests, would be an improvement over the present two-year plan. A good many bills opposing the coal industry are to be introduced, chief of which will be the coal-tonnage tax bill.

Heavy rains, followed by a mud slide caused a heavy slide of rock on the Stony Fork branch of the Louisville & Nashville R.R., near Middlesboro, on Jan. 15, one rock being reported so large that dynamite had to be used in breaking it up. The slide blocked the line and put the Crystal and lower Hignite mines out of commission temporarily.

Dan D. Walker, Jeffersonville, has been appointed manager of the **St. Bernard Mining Co.** for Louisville, New Albany and Jeffersonville. He succeeds William B. Gathright, who has retired after eighteen years with the company.

The Anchor Dean Coal Co., of Barbourville, capital \$10,000, has been chartered

by W. R. Lay, P. W. Golden and A. M. Decker, as an operating company.

With the December tonnage estimated production of coal in the Big Sandy field of Kentucky amounted to 7,125,490 tons in 1923, according to the Northeast Coal Association. In 1922 it was 6,133,077 tons.

George Marting, of the Logan Pocahontas Coal Co.; J. T. Bradley, of Jewett, Bigelow & Brooks, and R. R. Atkins, of the Liberty Coal & Coke Co., of Hazard, met with John P. White, former president of the United Mine Workers, and two others at the Hotel Gibson, Cincinnati, on Jan. 12-14 in the hope of finding a solution to a wage agreement that will have to be fixed for the men working in the territory of the **Kentucky-Tennessee Coal Operators' Association**. This association was formed following or during the strike of 1922 and the agreement expired. Those above were appointed arbitrators and their sessions were kept secret. It appears, however, that no point of contact was reached and it was decided to adjourn to meet on Feb. 4 at the same place in the hope that progress at the annual meeting of the Mine Workers at Indianapolis would open the way to a solution.

R. H. Davis, treasurer of the **United Collieries Co.**, of Ashland, has announced the purchase of Barney Nos. 1 and 2 mines on Beaver Creek, in eastern Kentucky.

NEW YORK

Rights to subscribe to the stock of the Lehigh Valley Coal Co. are expected to be listed on the New York Curb Market soon according to a statement made Jan. 17. The stockholders of the railroad company were offered rights to subscribe to the coal company stock on the basis of share for share of railroad stock held by them, plus a charge of \$1 for each share of coal company stock.

J. G. Allspach, Jr., recently was appointed sales manager in New York and New England for Camp, Osgood, Sleppy, Inc., of Scranton, Pa.

NEW MEXICO

The Phelps Dodge Corp. has embarked upon a thorough campaign of safety and first-aid training at its Stag Canon branch in Dawson. A class for miners is now organized which is expected to grow to a membership of 1,000. Also about 250 women in the coal communities and nearly 100 children are to have first-aid training.

OHIO

That Governor Donahey's appeal to the people of Ohio to burn Ohio-mined coal is bearing fruit is shown by conditions in the Hocking coal fields the past two weeks. In the Corning-Athens field, comprising about 50 mines, the output for the week ending Jan. 12 was 352,188 tons, as compared with 58,226 tons for the same period in December. There are about 1,200 fewer idle miners in this field than on Dec. 1. Storing of coal by railroads and factories in anticipation of a strike in April is said to be helping the situation.

The Blanchard-Zanesville Mining Co., a Pittsburgh concern, has made application to the United States Government for permission to construct a coal tippie, ice breakers, pile clusters and dredges in the Muskingum River at Ellis, 10 miles north of Zanesville, for the purpose of mining coal on a large scale for the Ohio Power Co.'s \$15,000,000 plant at Philo. The coal will be transported in a fleet of barges if permission is granted to the company.

Applications for permission to increase their capital stock have been filed with the Secretary of State by the **Oakley Coal & Supply Co.**, of Oakley, from \$100,000 to \$145,000; the **Ohio Coal & Supply Co.**, of Cleveland, from \$10,000 to \$200,000; and the **Hocking Valley Coal & Oil Co.** of Bellefontaine from 20 to 2,000 shares of stock, no par value designated.

The office of the **Puritan-Tuttle Coal Co.** has been succeeded by the **Tuttle Coal Corporation** in the Dixie Terminal Building, Cincinnati, a divorcement of the Tuttle from the Puritan interests having taken place. **The Pocahontas-Kanawha Coal Co.'s** office in the Dixie Terminal has been closed, the company's business being done through its Dayton office. The Kentucky & Virginia Coal Co. has opened for business in the First National Bank Building. **The Fayette Smokeless Coal Co.** of Mt. Hope, W. Va., has opened a selling office under the direction of Mr. Kirley in the Dixie Terminal Building.

PENNSYLVANIA

Charles D. Wells, of Scranton, has been appointed receiver for the **Buck Ridge Coal Co.**, operating an independent mine at Shamokin, which suspended Dec. 30 after failing to pay employees wages due them for the first two weeks of December. It is reported that \$70,000 in wages remain unpaid. The company is composed of New York men.

Suit for \$300,000 has been filed in Common Pleas Court by the **Pittsburgh & West Virginia Ry.**, against **John A. Bell**, banker and coal-land owner, in connection with the building of a branch line from the main track of the plaintiff company to property, owned by the defendant in the Cross Creek district, Brooke County, West Virginia, and Jefferson township, Washington County, Pennsylvania. The railroad alleges that after it had built a spur track at the request of Bell the defendant failed to open mines as he agreed to do, thereby occasioning a loss in the amount sued for.

John Markle was re-elected president and **A. B. Jessup** was named vice-president at the annual meeting of the **Jeddo-Highland Coal Co.**, held at Jeddo. There were no changes in the personnel of the board of directors. The company in 1923 produced more than 1,000,000 tons of coal. This is about the average and the corporation stands at the head of the independent operators in production. Gradual extension of the policy of electrification of the Jeddo-Highland Coal Co. mines is to be pushed until the whole chain of mines is eventually electrified.

George F. Osler has resigned his position as general superintendent of the **Carnegie Coal Co.**, of Pittsburgh, and accepted the position of vice-president, in charge of operations, with the **Pittsburgh Terminal Coal Co.**, with headquarters in the **Wabash Building**, Pittsburgh, to succeed **M. D. Kirk**, transferred.

Employees of Lehigh Coal & Navigation Co. and subsidiary companies have an opportunity to purchase stock of this concern. They can subscribe for stock at the rate of \$65 a share and the maximum number purchased is to be determined by the salary received by the individual. Subscriptions end Feb. 1, when allotments will be made.

Edward V. D'Inviillers, geologist and mining engineer, formerly located at 518 Walnut Street, Philadelphia, has formed a partnership with **Walter Gilman** and **J. B. Dilworth** under the name of **Edward V. D'Inviillers Engineering Co.**, with offices at 121 North Broad Street.

The Hillman Coal & Coke Co. of Pittsburgh, has begun cleaning up the Orient mine recently purchased at sheriff's sale, and is preparing it for operating. This company on Jan. 1, closed down its **Patterson** mine, near Elizabeth, for an indefinite period due to the dull condition of the coal market.

Arthur N. Young, of South Brownsville, inspector for the **Hillman Coal & Coke Co.**, was on Jan. 1 appointed superintendent of that company's recently acquired **Orient** plant, with headquarters at **Orient**, Fayette County.

John Lepitsky was recently fined \$10 and costs for taking matches and cigarettes into the **Francis** mine of the **Ford Collieries Co.**, **Curtisville**. This is the first prosecution brought in this locality in many years under the **Mine Protective Act** of 1911, which makes such an offense a misdemeanor.

William C. Hood, of Uniontown, assistant general superintendent of the **H. C. Frick Coke Co.**, has been elected to the board of directors of the **Merchants and Miners Bank** of Uniontown.

An indication that business is picking up in the **Connellsville** coke region is seen in the firing of 600 additional beehive coke ovens by the **H. C. Frick Coke Co.** last week. **The Oliver & Snyder Steel Co.**, which had been operating only about 40 per cent of its ovens, is now operating all of them. **The Hillman Coal & Coke Co.** has resumed operations at the **Warwick** mine, on the **Monongahela** River near **Masontown**, and is cleaning up the **Orient** mine, recently acquired at **Sheriff's** sale, preparatory to operating it. **The Pittsburgh & Erie Coal Co.'s** **Braznell** mine, which has been operating only two days a week for some time, resumed full operation last week. **The Poland Coal Co.** also recently resumed operations.

A State charter has been issued to the **Sullivan Flynn Coal Mining Co.**, of **Wilkes-Barre**. The company has a capital stock of \$200,000 and **Eugene Sullivan**, 1016 **Plane Street**, **Avoca**, is treasurer. The incorporators are **Eugene Sullivan**, **Edward M. Flynn**, **Avoca**, and **Margaret Flynn**, **Avoca**.

Other companies incorporated were the **Campbell Coal Co.**, **Ellwood**, \$25,000; **Oscar J. Zimmerman**, **Coraopolis**, treasurer, who with **Lester A. Campbell**, **Ellwood City**, and **Lola M. Zimmerman**, **Coraopolis**, incorporated the company; **Clyde E. Speer Coal Co., Inc.**, **Pittsburgh**, \$25,000; incorporators, **Clyde E. Speer**, 706 **Hastings Street**, **Pittsburgh**, treasurer; **Lee H. Funckem**, **Pittsburgh**, and **Joseph A. Richardson**, **Pittsburgh**.

Ten steel smokestacks 90 ft. high, over the steam-generating plant of the **Prospect colliery**, of the **Lehigh Valley Coal Co.** near **Wilkes-Barre**, were blown down by heavy winds on Jan. 16. Two men were injured. When the stacks fell the main steam lines supplying pump stations, fans and engine house with power snapped off. Steam locomotives used about the yards of the colliery were placed in position and furnished sufficient steam to start the fans after several hours' delay. With the fans shut down all men in the mines were notified to come to the surface. Colliery officials balanced the powerless cages with a coal car and scrap, raising one loaded with men and lowering the other loaded with ballast. This operation was repeated, the men at the bottom unloading the ballast from the down cage and getting on it themselves while those at the surface loaded the other cage with ballast of sufficient weight to lift the down cage. Men in the workings were hoisted to the surface in this manner.

A letter sent out by **A. T. Dice**, president of the **Reading Company**, and **W. J. Richards**, president of the **Philadelphia & Reading Coal & Iron Co.**, notifies holders of the general mortgage, 4 per cent gold bonds issued under the general mortgage of Jan. 5, 1897, that they have the right to surrender their bonds and receive in exchange \$666.66 principal amount of general and refunding mortgage 4½ per cent gold bonds, series A (or scrip certificates, as hereinafter provided), of the **Reading Company** issued under the mortgage and deed of trust dated Jan. 2, 1924, made by the **Reading Co.** to the **Central Union Trust Co.** of **New York**, trustee, and \$333.33 principal amount of refunding mortgage 5 per cent sinking fund gold bonds (or scrip certificates, as hereinafter provided) of the **Philadelphia & Reading Coal & Iron Co.** issued under the mortgage and deed of trust dated Jan. 2, 1924, made by the **Philadelphia & Reading Coal & Iron Co.** to the **Central Union Trust Co.** of **New York**, trustee, for each \$1,000 principal amount of general mortgage bonds so surrendered.

VIRGINIA

The New England Fuel & Transportation Co. has taken over the nine steamers formerly operated by **Crowell & Thurlow**, and will put them exclusively in the **Hampton Roads-New England** coal trade for the **New England Coal & Coke Co.** It is one of the largest single fleets of ships now in the coastwise trade.

WASHINGTON

The Roslyn mining field went through the year 1923 without a fatal accident, **John E. Morgan**, an operator, recently reported.

"Snowbirds" in the **Seattle** region are offering more serious competition than ever before. No less than twenty-eight in **Seattle** alone have formed an association and claim to be buying **Utah** and **British Columbia** coal in steady volume. They have undercut the market about \$1.50. **F. H. Benton**, of the **Consumers Fuel Co.**, is one of the organizers of the group.

WEST VIRGINIA

It has been announced by **C. F. Keeney**, president of **District 17**, **United Mine Workers**, that **R. M. Williams**, of **Morgantown**, an insurgent leader in the **United Mine Workers**, was elected vice-president of the district over **William Petry**, the present incumbent, and **Nick Aeillo**, in the special election held in December. **Petry** was elected vice-president at the regular election held in December, 1922, but soon after **Williams** made the claim that he had been debarred as a candidate when his name was removed from the ballot by the district board. He started a movement for a special election.

The Wyatt Coal Co. recently won a suit in the **U. S. District Court** for the **Southern District of West Virginia**, in which it was a defendant. The suit was brought by the **Detroit Edison Co.**, which asked damages

for alleged non-delivery of coal on contracts for 1916 and 1917. The verdict in the case was returned at the instance of the court.

Preparations are well under way for the opening of a new mine at **Chapmansville** by the **Dwyer Coal Co.** The company has obtained a lease on 500 acres of coal land in **Logan County**. Two openings have been driven and in driving a third opening the company will operate in the **Alma** seam, having a vein 5 ft. thick. Work has progressed to a point where it has been possible to lay the tracks 300 ft. within the mine as well as to the base of the hill where the tippie is to be located. That structure will be equipped with shaker screens and other equipment for the preparation of coal. It will be necessary to lay only about 100 ft. of rails to reach the mine from the **Chesapeake & Ohio** and it is proposed to put in a two-end siding with three tracks. In addition to a club house and other plant structures, the company is preparing to build a number of five-room houses for miners, with hot and cold water and provided with other conveniences. The company has made provision for an adequate water supply by building a concrete reservoir on the side of the hill and also has installed a sewage system. This corporation is capitalized at \$100,000. The president of the company is **John G. Dwyer** and **J. W. Dwyer** is secretary and treasurer. The **Dwyer** brothers were among the early operators in the **Greenbrier** field and have also operated mines in the **Kanawha** and **New River** fields.

Ejection of nineteen miners occupying dwellings belonging to the **Francois Coal Co.** in the **Harrison County** field is sought, the company desiring to gain possession of its houses in order that miners who will work in an open shop or non-union mine may be employed. Change in the labor status of the mine, it is indicated in the proceedings, follows the leasing of the company's mine at **Norwood**, to the **Turkey Run Coal Co.** After hearing the testimony, **Magistrate Kidd** took the case under advisement and will announce his decision later.

The Bonafide Coal Co. will operate in the vicinity of **Tunnelton**, in the **Preston County** field, having just been organized with a capital stock of \$125,000. Among those interested in the new concern are **Guy M.** and **Alberlee C. Bonafide**, **John F.** and **Lola F. McKone** and **C. M. Eliason**.

CANADA

The Vancouver City (B. C.) Harbor Commissioners have announced that coal bunkers are to be constructed at the Port of **Vancouver** at a cost of about \$500,000. They are designed to handle shipments from the interior of the province as well as from the **Province of Alberta** and the **Vancouver Island** field. It is recognized that to be a great grain export center and shipping port **Vancouver** must have fueling accommodations for ships making long voyages. It also is thought that **United States Pacific** ports will be in the market for higher grade steam coals.

Coal operators of **British Columbia** are meeting with competition in the domestic market from the products of the coal fields adjacent to the **City of Bellingham, Wash.** This has been classified as lignite, or lignite dust, by the customs officials and so is being admitted to **Canada** free of duty.

It would appear as if the problem on carbonizing **Saskatchewan lignite** is being solved. The new **Hood-Odell** oven erected at the lignite utilization plant at **Bienfait, Sask.**, is turning out char in large quantities and complete success has been attained in briquetting it at the briquetting plant at **Hebron, North Dakota**, where two carloads of briquets have been manufactured. One carload was distributed to householders in **Regina**. Exhaustive tests will be carried out at **Ottawa** under government auspices.

The Dominion Coal Co., Ltd. has declared a dividend at the rate of 1½ per cent upon the preferred stock of the company, payable Feb. 1, to shareholders of record on Jan. 12.

J. E. McLurg, has been appointed vice president of the **British Empire Steel Corporation**, and will reside in **Sydney**. **Mr. McLurg**, who has been general manager of the **Halifax Shipyards Co.**, a subsidiary of the **British Empire Steel Corporation**, succeeds **D. H. McDougall**. Since the retirement of **Mr. McDougall**, **H. J. McCann**, former assistant general manager of the company, has been in charge of coal-mining operations. **Mr. McCann** has been in ill health for some years.

New Equipment

Bulldog Trolley Clamp

The outstanding feature of the Ohio Brass Co. new bulldog trolley clamp is the automatic operation of the jaws in opening when the nut is turned to the left. Ordinarily one thinks of clamping the jaws to the wire only with the nut, leaving the problem of preparing the jaws for taking the wire to the man who makes the installation. Anyone who has tried the combination of lifting the trolley wire into place, manipulating the wrench and at the same time trying to hold the clamp jaw apart will readily see the importance of this new feature. The nut can be set to open and hold the jaws ready for receiving the particular size wire to be used.

The design is simple, consisting of only five parts, nut, stud, two jaws and a high-strength steel hinge pin. The assembly provides for great holding power, and offers a pleasing appearance. One size of the clamp will take care of all the usual figure 8 and

TROLLEY CLAMP EASY TO INSTALL

The nut on the top holds the jaws open, thus enabling the workman to place the wire in the clamp with ease.

grooved wire sizes without changing the jaws. Another size with different shaped jaws takes all ordinary sizes of round wire.

Waugh Comparascope

The Waugh Comparascope, manufactured by the Denver Rock Drill Manufacturing Co., of Denver, Colo., was designed to simplify the process of forging and heat-treating drill steel so as to obtain the highest efficiency in drilling and to insure durability of the drill steel. By the use of this instrument it is possible for the blacksmith to heat-treat his drill steel easily with speed and precision.

Steels when heated to various temperatures have certain definite colors corresponding to the hardening temperatures. Therefore heat-treating is very much a matter of color comparison. The varying shades which the steel

takes when heated are almost imperceptible, so the comparascope has been developed to enable the blacksmith to match the color shown by the comparascope with the color of the steel that he is heating.

The Comparascope is connected to an

INSTRUMENT FOR ASSISTING THE WORK OF TEMPERING STEEL

By comparing the color of the heated steel with the color indicated by this device—for that particular grade of steel—it is possible to heat-treat the material to the desired degree of hardness.

electric-light cord and the current heats a small coil of high-resistance wire, visible through a lens in the center of the apparatus, to any desired temperature color, the blacksmith comparing his steel when heated. The coil has a fixed resistance and is connected in series with a variable resistance, which in turn is connected with various plug connections on the front of the unit.

To further aid in the process of hardening steel, a high-grade permanent magnet is suspended at the center of the instrument immediately below the radiating coil. This magnetic indicator shows the magnetic condition of the steel, which is another indication of the hardness to which the steel will temper.

When the carbon content of drill steel is known, forging and hardening temperatures are quickly and easily determinable. By plugging into the socket having a carbon content corresponding to the material being worked, as indicated on the directions plate, the Comparascope shows the proper color to which the steel should be heated. The magnet is very useful when the carbon content of the steel is not known. If the magnet is attracted to the steel, the change point—that is, the hardening temperature—has not

been reached. By first heating the material to a low red heat and increasing its temperature and testing with a magnet, the temperature of the steel may be raised until the test shows no attraction of the magnet.

Light-Weight Electric Valve Grinder

The new No. 1 slow-speed Black & Decker electric valve grinder is similar in all respects to the valve grinder previously produced by this company except that it embodies many refinements. It weighs only 6 lb. and is arranged with a double gear reduction to give what has been ascertained by experiment to be the most efficient grinding speed.

It is equipped with the most improved designed pistol grip and trigger switch and particular attention has been given to the elimination of vibration, so that it can be used with the greatest of ease and comfort by the mechanic.

The manufacturers are now making tools for this machine, and will be able to make deliveries in large quantities within a very few weeks. The Black & Decker Manufacturing Co., of Towson Heights, Baltimore, Md., makers of the grinder, give the following example to show the value of this tool to the automotive maintenance man from a dollars and cents standpoint:

"If an eight-cylinder car requires one man's labor for five hours to perform the actual valve grinding operation and he charges his customer \$1.25 per hour he will have to charge \$6.25 for the grinding work. As the new valve grinder performs the work more than four times as fast as it can be done by hand, the same man can grind the valves on at least four eight-cylinder motors in the same length of time, five hours."

ELECTRIC VALVE GRINDER

Increasing the work per man per day, resulting in more productive effort is real labor saving. This equipment sells its own value.

NEW YORK, JANUARY 31, 1924

Number 5

How Mr. Lewis Favors Machines

ON ANOTHER page John L. Lewis, president of the United Mine Workers, denies that the union opposes the introduction of labor-saving machinery. With entire willingness to be fair with Mr. Lewis, it is still easy to say that what Mr. Lewis says is largely fluff. The union favors such machinery but insists, he says, only upon receiving a fair share of the benefits in the form of wages. What is a fair share? Therein, of course, lies the nub of the situation. Judging by the recent Kansas cutting-machine case, the union's idea of a fair share is peculiar. The operators were willing to agree upon a machine differential of eleven cents, but the miners would not recede below five cents. So there is no machine scale in that state and the field is deprived of the economic advantage of machine mining.

Somebody is responsible. Mr. Lewis would say the operators are at fault for their grasping efforts. Somehow we cannot see it that way. Paying a machine runner only five cents a ton less than the hand mining scale is not our idea of a fair division of the benefits of machine mining. This sort of "fairness" on the part of organization is the direct means by which the union has delayed and handicapped labor-saving machines. It would be encouraging if the union's idea of fairness were to change with regard to the introduction of loading machines. The time is upon us when a loader scale must be fixed.

"The Won'ts"

A PREVALENT ailment in the coal industry is "the won'ts." Too many good men in coal "won't" help educate the public, "won't" meet the critic of the business halfway, "won't" recognize that perhaps something ought to be done at Washington about coal, "won't" this and "won't" that. In the present session of Congress they are interested only in blocking legislation that is offered—if they are interested at all. They are not trying to propose anything helpful. They do not purpose telling Congress or the nation what the coal man really wants. They are merely going to tell what the coal man does not want.

Of course defense against improper coal legislation is important. But it is unfortunate that, paralleling all the defense now being marshaled, there is so little offense. There is so little of it, in fact, that no ordinary citizen could say what the coal man's program is; nor could the ordinary coal man define it. There isn't any program. "Let coal alone" is as near an approach to it as can easily be set up in words. But that is a poor program to be frankly adopted by coal men who, everywhere, have been admitting there are all sorts of ills afflicting their industry. If there are all these ills, there must be ideas for cures.

What are these ideas? They ought to be laid before

the congressional representatives of every state in the Union, and laid there in sincerity. On the other side of the fence politicians and grandstanders, and honest but deluded gentlemen are saying and doing plenty about coal; but what constructive thing is coal doing for itself? Altogether too little. It is cheerful to note even so small an effort as is now starting among a little group of Midwestern operators. That few intend to say something constructive to Congress about coal, even at the risk of not getting much of a hearing.

They are going to say what they think would do coal some good, whether the rest of the industry agrees with them or not. They are at least constructives. They are not stricken dumb by "the won'ts," and that's something in their favor.

Man to Man

WHAT is the operator of a coal property to his men? What are the men to the coal operator? Only too little too often. A railroad president, Sir Henry Thornton, operating a 22,000-mile system, the Canadian National Railways, speaking at the Bond Club in New York City a few days back detailed a way in which he proposed to keep in touch with the thousands of men under his direction scattered over an area almost as large as the United States—only "almost as large," for only part of Canada is netted with railroads.

He said he intended to establish a "chain of broadcasting stations from the Atlantic to the Pacific at such intervals as will enable headquarters to keep in constant touch with the whole of the property." He added: "We propose to place at the disposal of our employees wireless sets for a moderate price. The sets can be bought either by paying for the entire outfit at once or at the rate of \$1 or \$2 a month. The result will be that in a comparatively short time most of our men will have equipped themselves with wireless sets, and we propose, as fast as circumstances may require, to talk to our men in the evenings at their own homes. I propose, myself, as president of the company, to speak at least once a week to our men."

Think what might be done in the coal industry if this were tried by the right kind of man, one who looked upon himself as one of the gang by which the job of mining coal was being done, a red-blooded man among red-blooded men helping to do a work that was worth the doing, inspiring other men to work with him in doing just that kind of work, thinking with them, of them and for them.

What would it not do for safety! How strongly would the message of saving one's life for the sake of the family and for the good of humanity ring through the air! Every man lives for accomplishment in the home and in the community. How earnestly could the message of avoiding injury be impressed on

those men in the virile words and convincing tone of a man moved by ambitions like those of his hearers!

What would it do for coal preparation, for co-ordination between various units in the organization, for clearing up misunderstandings. Out of it would come a new team work. The larger aggregations would re-align themselves into a body of men with one aim and purpose, inspired by a community of interest, actuated by a common ideal. It is no pipe dream. Some might not be able to carry that message; they are the men who have none, who have no common purpose with their men, who are ill fitted to be leaders. But to those who have the power of leadership the radio furnishes a voice, the *vox humana*. No more powerful tool for good—or for evil—has ever been devised.

Putting the "Eagle" on Coal

EVEN when a manufacturer has a monopoly it pays him to make a good article. He finds it brings him larger business and the amiable regard of the public. Had the manufacturer made the automobile a wheezy, rattling and uncertain means of travel the automotive industry would never have made the progress it has.

When, however, a product is competitive, like coal, it pays even more for every producer to make a good article and to have a ready way of convincing the public that his is a reputable product. No better way can be found than to get the indorsement of the industry corporately expressed or, better yet, to get the approval of the government.

When the goldsmith craftsmen of Great Britain found their product looked upon with suspicion because some of the dishonest workmen put excessive quantities of dross in their gold, they arranged to have their guild assay all gold and put a stamp upon it to show how much dross was mixed with it, dross being necessary in the metal because otherwise it would not be hard enough for any use. More dross is advisable where the metal is subject to much wear.

It would pay the coal operators to have their coal similarly assayed, so that the buyer would know what he was getting. Some coal is inherently less efficient than other, some is necessarily higher in ash or sulphur, some of it is not suited to boilers having high rating; but whatever the coal may be, the purchaser should know just what it is and the best of guarantees should be placed on it so that it could be bought with assurance.

To take an example from the publishing industry, a bureau has been created to find and record the size and character of the circulation of periodicals for those interested in knowing these facts. Is it paid or unpaid? Is it paid to date or does it consist of persons who are being carried along long after their subscription has lapsed? What is the character of the readers among whom it circulates? The larger publishers nearly all submit to this inquiry, for they have nothing to hide.

Similarly the coal operator with a good product with nothing to disguise, who has taken the dirt out of his coal, prepared it and perhaps washed it, wants the public to know that he has a good article. He would welcome the approval of a guild or bureau or the United States Government.

Some time ago O. P. Hood, mechanical engineer of the U. S. Bureau of Mines, advocated that any company that requested the Bureau so to act should have the product in several of its cars in various parts of the

country sampled at random. The Bureau would not take samples in cars indicated by the operator but take its own pick of all the cars shipped. It would then determine by this investigation the rating of the mine from which the cars came, that rating being above or below a correct rate of the coal in the face of the mine according to the degree of cleaning.

The mine would be permitted to sell the coal as being of a quality vouched for by the government, but should it prove in analyses of samples taken frequently thereafter that the rating should be lower or higher, a new rating would be issued, and the mine, whether it wished or not, would be obliged so long as it quoted the government approval to announce its rating so that all the world would know if the coal from that time was 12, 14 or 18 carat, so to speak.

The mine that failed to get government approval would find the going hard. It would be as difficult to sell such coal as it would be to pass a gold dollar which did not have the government's stamp of approval. The mine owner with the uninspected coal might soon have to leave the market, and dealers who failed to say that they sold only coal which was under the government cachet would automatically be ruled out of the market.

Definitions

SOME years ago it was decided in Great Britain that the coal industry should be put on the six-hour day and the mines nationalized. The day was reduced from eight to seven hours and when the suggestion was made that the industry would be better off for a change back to the longer working day, the labor leaders gave notice that they had not abandoned the six-hour day. Now that the Labor Party in England is second strongest and may become first there are some interesting questions arising.

Should the Labor Party take over the government they must carry out the policy of nationalization of mines and railroads, policies they have sponsored for years. But they have no clear conception of what they mean by nationalization of these industries. Their leaders are divided on definitions and schemes. Some, the more moderate laborites, profess to believe that nationalization can be interpreted to mean state control for the benefit and support of the entire community. Others maintain that what they mean by nationalization is "control by the workers." They likewise are divided on the question as to whether they intend to confiscate the property or compensate the owners.

JOHN LEWIS IS STAMPING ON ONE BRAND OF RADICALISM, if evidences displayed at the Indianapolis convention mean anything. Whereas two years ago the radical vote all but beat the United Mine Workers' administration, this year, on such important radical issues as the reinstatement of the Red and recalcitrant Livingston and McLachlan, of Nova Scotia, the recognition of Soviet Russia, and the alliance of the union with an all-labor political party, Lewis' forces soundly defeated the advocates of these measures. However, this does not mean there is less bolshevism in union ranks. It means there is less defection among big union leaders. Bringing Frank Farrington, of Illinois, into camp a year or so ago is the real reason. The bolshevist sentiment is still in the union but it lacks a powerful enemy of Lewis around whom to rally.

Making Coal-Loading Machines Work Successfully in Indiana

Ayrshire Coal Co. Cuts Loading Costs Even on Room-and-Pillar System with Machines Averaging but 75 tons Daily—With Snubbing More Lump Is Obtained Than With Hand Loading—Some Loader Speculations

BY DAVID INGLE*
Evansville, Ind.

IT'S "FASCINATING"

It is fine that so many American coal operators have a pioneering spirit—a spirit that drives them to do by their own ingenuity the thing the other fellow thinks is impossible. There is a certain adventure into the unknown for Mr. Ingle, for instance, as he toils and cudgels his brain over the problems of fitting machine loaders into his mines. He calls it a "fascinating experiment." But he and many other mine operators all over the land must toil and cudgel their brains and invest their money and lie awake nights over this revolutionary machine, the underground loader. Nothing else will ever make it meet the conditions of this country. Inventors and manufacturers can do only a small part of it. The operator and the practical mining man, meeting heart-breaking obstacles in the path of their great adventure in loading, are making the new machine revolutionize coal mining. In the fascination of the quest lies the future of machine mining.

though we have a long way yet to go.

This mine, Ayrshire No. 6, was opened in 1917 on a coal tract of 200 acres lying near the railroad, but inaccessible from any of our other operations. During the war we worked this mine up to a production of about 800 tons per day. In January, 1921, the mine was closed down because we didn't need the tonnage from it, and because it was the one we could maintain idle with the least expense.

When we decided to try mechanical loading this idle mine seemed the natural place to try the experiment. The coal there is 5 ft. thick,

overlaid by a gray shale which is not reliable, standing fairly well in entries but requiring close timbering in wide working places. The fireclay bottom in places is soft and wet. The thickness of the overlying strata runs from 35 to 70 ft., and this accounts both for the uncertain roof and the quantity of water in the mine.

FOR several years our company watched with interest the progress of mechanical loading of coal in mines. In December, 1922, we made our first entry into the loading-machine game by installing two loaders in one of our mines that had been lying idle for nearly two years. Later four more were added. The six machines and the method of using them in this mine have been developed to a point that enables them now to load out an average of 75 tons a day operating on a room-and-pillar basis, and their service is improving steadily. Already coal is produced cheaper at this mine than it ever was under the hand-loading system, the proportion of lump coal is higher, and we are fairly well satisfied with the results we are getting in this venture in machine loading, even

*President and treasurer, Ayrshire Coal Company, Oakland City, Ind.

The coal itself is of good quality, running only about 1.25 per cent sulphur and 6 per cent ash, with no partings of any kind. The mine was opened and worked by the usual room and pillar method, and the coal was all undercut by machines.

We started the two Joy machines working in rooms and entries that had been standing idle for nearly two years, and our first discovery was that the little loaders,

How Room Necks Are Turned

Making the turn at an angle of 45 deg. to the haulageway not only maintains the narrow necks necessary for the support of bad roof but enables the long loading machines to enter without hitting the ribs.

could get a foothold we had no further trouble of this kind.

We have tried operating various widths of working places and found that the best way, so far, to operate this particular loader in our coal is by regular room-and-pillar methods, with the room necks turned off the entry at 45 deg., in order to give the long loader a chance to get into the corners of the rooms. We are driving these rooms, where we can, about 24 ft. wide, leaving pillars between them from 6 to 8 ft. thick. Owing to the bad roof, it has been necessary usually to timber pretty close and to reneck many rooms. This has interfered greatly, preventing the attainment of results that the loaders might have afforded had the layout originally been made for their accommodation.

The cars used at this mine hold about $1\frac{1}{2}$ tons as loaded by the machines. The tops are merely rounded up, as the loaders put the coal on the cars too quickly to permit of building. The loading machines are kept supplied with cars by mules, one mule and a driver being provided for each loader. The empty car is brought by the mule to the turnout, which is placed just as close to the loader as can be arranged conveniently. The mule is then hooked to the loaded car, and as soon as the load is pulled out, the loader's helper shifts the empty car by hand to the loading position.

Two men are used on each loader, one to operate the machine itself and the other, a helper, to lend a hand wherever needed, his main job being to shift the empty car to the loader, to shift it as it is being loaded, and to keep in shape the loose rails on which it stands. These loose rails are fastened at one end only, usually by steel ties, which are readily clamped to, and loosened from, the rail.

Of course, all the coal is undercut and shot down before the loader tackles it. In this mine one undercutting machine can easily cut all the coal two loading machines will handle, and the operation is conducted on that basis—one undercutter for each two loaders. Five or six loading places are allotted to each loader, principally in order that the cutting machine may keep plenty of coal cut ahead. Two men are used on the undercut-

ter, operating on soft, wet and partly heaved fireclay bottom, promptly tried to dig themselves in. We provided some heavy planking on which they could get a start, and after they had loaded out two or three falls of coal and had advanced far enough into a working place on freshly uncovered bottom so that the caterpillar treads

ter. One man drills, makes the cartridges, tamps, and shoots for two loaders. This means that he drills, tamps and shoots anywhere from 15 to 30 holes a day, for in wide places we drill three holes over the coal.

Additional loaders have been installed from time to time, and at present, practically a year from our start, we are using six of them. Each of these loaders is producing, at present, an average of about 50 cars, or 75 tons, per day, making the day's hoist about 450 tons. This is much better than was done at first and is fairly satisfactory, but we hope to improve as we learn more.

To operate this mine, with its six loaders, the following 53 men are employed at present:

- 1 Mine boss,
- 1 Electrician,
- 1 Machine-repair man,
- 1 Dumper at shaft bottom,
- 1 Coupler at shaft bottom,
- 2 Motor men and trip riders,
- 3 Tracklayers,
- 2 Pumps,
- 6 Jerry and timber men,
- 6 Drivers,
- 3 Shotfirers,
- 2 Snubbers,
- 6 Loader operators,
- 6 Loaders' helpers,
- 6 Cutters and cutters' helpers,
- 1 Top boss,
- 1 Blacksmith,
- 3 Railroad-car trimmers and yardmen,
- 1 Stable boss.

The coal is dumped into a hopper at the bottom of the shaft, and hoisted by a continuous bucket elevator, so no engineer or fireman enters into the calculations. The dumper also is the weigh master.

We have found many interesting things as the work has progressed; in fact, it is quite a fascinating experiment. In this mine conditions are far from ideal. Reference already has been made to the bad roof. It is so bad that less than half the working places are as much as 15 ft. wide. So much narrow work involves moving the loader from place to place too often and diminishes seriously the available time for the actual loading of coal. Roof conditions are a much more important factor in mechanical loading than they are when the loading is done by hand with a shovel.

For quite a while one of the major difficulties encountered was that of getting coal out of the corners of the working place with the loader. It seemed that in an average room-full of coal with, say, a 22- to 24-ft. face, having perhaps 30 tons of coal in each fall, it would take longer to load out the 5 tons or so in each corner of the room than it did to load out the 20 tons in the middle. The coal in the corners would be wedged in tight and hard to get down.

Recently this trouble has been almost entirely overcome by the simple process of snubbing each cut of coal before it is shot. The snubbing allows the powder to roll the coal over as the latter falls and seems to do away with the tight corners. Also much less powder is required to shoot a well-snubbed shot, and a much better percentage of lump coal is recovered.

Of course it costs something to do this snubbing, and the cost and the results obtained may not be so marked in inverse proportion in other mines and other coals, but it is very successful with us. Perhaps equally good results in this respect may be obtained by shearing either one end or the center of a room that has been undercut. We expect to try this out also when we get around to it.

One rather gathers the idea, from reading of the performance of loading machines, that the great difficulty in mechanical loading would be to keep empty cars supplied to the loader. So far, this has been one of the

least of our troubles, even though our cars are small as cars go nowadays. One driver with his mule could easily supply from 25 to 40 per cent more cars to our loaders than they have used so far, provided his track is in good shape and the train locomotive keeps cars on his parting for him. Not that the importance of transportation is to be minimized for a moment, but thus far it is the narrow work, close timbering, and soft bottom that have held us back and not transportation.

We believe that the loaders would work to much better advantage under good roof. A hard, smooth bottom greatly facilitates the operation of any kind of loading device, and, of course, one would expect proportionally greater results in a thick bed of coal than in a thin one, because it would enable the loader to handle a larger tonnage with less moving.

In spite of the adverse physical mining conditions under which we are operating, we are loading coal with our machines at somewhat less expense in this mine than it costs us to load by hand in our other mines, where similar physical conditions prevail. This reduction is enough to lower the total cost of producing coal even though the company does all drilling and shooting.

Many types of mechanical loaders are now in process of development and many are in actual use. We have had actual experience only with the Joy, but there are enough machines operating under diverse conditions to show that the mechanical loader is a thoroughly practical device. We have found some weak places in it, but these details have been promptly remedied in every instance by the makers, the operating results continually improving.

We are operating entirely with union labor, and the union has offered no objection to the introduction of these machines. Our men seem to like to work with them. After all, it is much better to let electricity do the hard, heavy work than to get human energy to perform it. Though it takes an able-bodied man to operate a Joy loader successfully, it certainly requires no more muscular effort to handle it efficiently than it does to

operate any of the standard undercutters now so universally used.

If the loading machine does away with the old back-breaking shovel, naturally the man who graduates to it from the hand shovel will like the change. If the use of mechanical loaders will enable a mine worker to realize just as much for his day's work, and come out of the mine at the end of his shift less tired, he is bound to be for it, when he learns about it. And if its use enables the miner to earn just as much and enables the coal operator to reduce the final cost of coal to the consumer, it will then have become no longer an experiment but will be a necessity.

Of course there are apparent disadvantages connected with the use of mechanical loaders. One of them is that coal is loaded too rapidly to permit the impurities to be removed while loading is actually going on. This can and is being done more or less successfully in loading by hand. Mechanically loaded coal must be picked and cleaned outside of the mine on loading booms and picking tables and by crushing and mechanical separation of the impurities. A dirty seam of coal loaded by machines will not be successfully marketed unless an elaborate cleaning equipment is provided in the tipple.

An objection that has been urged is that it will be necessary to shoot the coal too hard, and get it all down in a pile before a loader can handle it successfully. We found this true at first, but by snubbing and studying our methods of shooting we have succeeded in turning out just as good or a larger percentage of lump coal than before the loaders were used. And I am sure we will do still better in that respect in the future.

Still another objection, and a formidable one just now when the industry is so demoralized by overproduction and ruinous competition, is the cost of the machines themselves and the auxiliary equipment necessary to their proper exploitation.

To completely equip one of our modern 4,000-ton mines with Joy loaders would increase the invested capital in that mine by from \$250,000 to \$300,000,

This Machine Proves Economical Though It Averages But 75 Tons a Day

Six like it are operating in room and pillar mining in Ayrshire No. 6 and their tonnages are increasing as various changes in method are made to benefit them. The scheme of delivering cars to the loaders is 40 per cent ahead of the rest of the system, so there is no handicap there. Roof falls and too frequent machine moves due to narrow working places are the most severe checks on the loaders.

assuming that the loaders would turn out 100 tons each per day, which is more than we have been able to do to date.

It is fair to assume, however, that this initial expense will be offset to a large extent by a saving in development owing to the greater concentration of work that is possible by the use of loaders.

Working on the room-and-pillar system, in vogue in Indiana and elsewhere, to produce 4,000 tons per day would involve perhaps 500 to 600 working places. Operating, say, 40 loaders, the number of working places to produce the same tonnage might easily be held down to 200 to 250, or 40 per cent of the number now required for hand loading.

Fewer mine cars would be needed and less steel rail, although probably more mules or locomotives would have to be provided. The consumption of power in operation probably would be increased, but not so much as might be imagined. We do not notice as yet any marked increase in this respect, but it is reasonable to anticipate that machines which must be operated almost continuously during the shift will increase power consumption noticeably, and of course the loader must operate if it is to be efficient.

Most of the foregoing is written with the idea that the work of the loader is done on a room-and-pillar system. That is the only plan we have tried effectively so

far. But it is doubtful indeed whether the future coal loader will work on this system. It would seem that a continuous working face would be much more productive of tonnage.

I do not at this time know enough about the possibilities of working a continuous, or longwall, face to hazard much of a guess as to its merits. But of course the greatest advantage apparent in such a plan would be the ability to load an uninterrupted train of cars, reducing the delay due to the shifting of loads and empties.

LOADER NOW PAST EXPERIMENTAL STAGE

The development of machine loading is coming rapidly. I have no hesitation in saying that the machine we are using is past the experimental stage, and is an established dependable loading unit; it is being made in quantity. The loss of time from breakdowns is not much greater than in other heavy-duty mining machinery like undercutters and gathering locomotives.

The industry daily evinces greater interest in the subject. Hardly a day passes that we do not have visitors at this little mine. The boys have gotten so used to them that they do not even "play to the galleries" any more. It is all part of the day's work. Operators, miners and the public from all parts of the district come to look the proposition over, and they are all welcome.

The Miner's Torch

Certificates of Competence?

THE State of Connecticut has been receiving much distasteful publicity recently because some members of its medical examining board are under indictment for furnishing copies of examination questions in advance of the examinations, thus allowing "quacks" to qualify as physicians.

It would be pretty hard to think of a more despicable crime, and when one considers that at best the bribe money they receive could not have been considerable it seems rather hard to believe that any state official could stoop so low. In fact I have heard people, in discussing the press comments, argue that they never could be made to believe that men with enough standing to have been appointed on such a board could possibly be led to stoop so low.

I only wish that my contact with public officials could have been of a nature to make me feel that way about it, but while I was listening to such sentiments being passed I recalled, unfortunately, that once when I was a young man I knew of my own knowledge that a state mine-foreman's examining board allowed its questions to get out in advance so that a few favored ones could be sure of passing the examination. If an incompetent mine foreman is not capable of doing as much damage as an incompetent physician I miss my guess.

Personally, since that time I have never considered certificates of competency of any description of much value and I have always been glad that I came to that conclusion early in life because it has allowed me to explain to my own satisfaction many otherwise unex-

plainable errors of supposedly trained men with whom I have been thrown.

I recall, for example, several camp physicians employed by some of the companies for whom I have worked who, if they still are holding similar positions, are undoubtedly feeling very uncomfortable as this Connecticut publicity spreads around, and they do not live in Connecticut either. I never questioned their certificates or their diplomas but I questioned their abilities and I feel sure they have made little change for the better in the years that have passed since I was in close contact with them.

Let me hasten to add that I have no desire to offer an argument against the advisability or necessity of having state boards pass on the competency of physicians, mine foremen or other men having equivalent responsibilities to the public; but the okehs of such boards should be taken only for what they are worth.

The mine foreman examining-board leak that I knew about "of my own knowledge," as the lawyers would say, was not one that could be traced back to a money bribe, but it was chargeable to a popular and influential mining official's pull with the board; he had two men due to come before the board and he was uneasy about their chances of passing on examination and yet was anxious to have them pass because they were men whose services he required.

Just how he persuaded the board to do his bidding I do not know but I saw the questions the day before the examination and they were in the hands of one of the men who were to take the test. The man with the pull and the men who profited by his efforts have all been dead quite a number of years and, so far as I know, no harm ever came of the adventure; otherwise I would not record it here. Possibly you are wondering why the man who obtained the questions showed them to me the day before the examination. Very easily explained—the questions were of no value unless someone worked up the answers, and he thought that I could help him.

Heavy Shot of Coal in Anthracite Mine

Classification of Coal That Will Enable Buyer to Know What Kind of Fuel He Is Getting

Suggested That Coals Be Divided Into Ten Classes by Percentages of Fixed Carbon with the Ash Equated to Seven per Cent—Seven New Classes Added to Recognized Divisions—Graded Also for Quality

BY GEORGE H. ASHLEY
State Geologist, Harrisburg, Pa.

COAL has been much in the public eye in recent months, and the eye has not been altogether friendly. The complaints have been uncertain supply, high prices and uncertain or low-grade product. This paper deals with the last problem only. The first step toward meeting that problem must be an understanding among coal men as to what constitutes superior, good, fair and poor grades of coal, and the formal designation and adoption of standards for grading coal. Tied up with this question of coal grades is the larger, though possibly no more important, problem of the standardization, definition and naming of kinds and classes of coals.

I have been studying this problem for the last six years and have published several preliminary drafts of proposed schemes of coal classification and grading, which have been followed by a voluminous correspondence. Studies and correspondence have shown that while the classification first presented more than four

years ago was technically correct it was too complicated to be of the greatest service. This paper, prepared at the suggestion of the Executive Board of the Coal Mining Institute of America, presents the same scheme of classification reduced to its lowest and simplest terms.

Today one does not call his dealer and order "a ton of coal." The class and size and perhaps the grade are specified, for experience has shown that certain kinds or types of coal are best suited to certain uses. Furthermore, coals from different localities vary widely in physical and chemical characteristics and in adaptability to various uses. The most easily recognized classes and types have been long recognized and named as cannel coal, coking coal, anthracite, brown coal or lignite, and so on; or local names have been used to designate coals, as Clearfield, Pocahontas, Pittsburgh, Youghioghenny gas, Sea coal, Brazil block, and so on.

Many attempts have been made to classify coals both here and abroad. In Table I will be found examples of classifications that have formerly served the industries.

Detailed classifications of the lignites have been made by several German authors, and many of the distinctions made are commonly recognized in the coal fields. These classifications divide the lignites into four to

An article entitled "A Practical Classification for the World's Coals," presented at the December (1923) meeting of the Coal Mining Institute of America. A committee consisting of A. C. Fieldner, W. E. Fohl, A. R. Pollock, E. A. Holbrook, F. B. Lockhart and J. J. Rutledge was appointed by the institute to confer with Mr. Ashley and report on a classification that could be used in the marketing of the world's coal resources.

TABLE I—SELECTED CLASSIFICATIONS OF COALS AS FORMERLY USED

<i>Ure (Dictionary of Arts, etc.), 1845</i>	
(1) Cubical coal—(a) Open burning (b) Caking	
(2) Slate or splint coal	
(3) Cannel coal	
(4) Glance coal (anthracite)	
<i>Watts Dictionary of Chemistry.</i>	
(1) Lignite or brown coal	
(2) Bituminous or caking coals—(a) caking coal, (b) cherry coal ("does not fuse"), (c) splint, rough or hard coal, (d) cannel coal	
(3) Anthracite, stone coal or culm	
(4) Steam coal	
<i>H. D. Rogers, 1858.</i>	
Anthracite	Hard or dry (volatile matter below 6 per cent) Semi or gaseous (volatile matter below 10 per cent)
Common Bituminous coal	Semi-bituminous (volatile matter between 12 and 18 per cent) bituminous (volatile matter about 18 per cent)
Hydrogeneous or gas coal	Cannel coal (minimum yield of gas 9,000 cu.ft. per ton) Shaly (Torbanhill) Asphaltic (Albert mine)

Persifer Fraser, Jr., 1877.

(Based on "fuel ratios," or fixed carbon divided by volatile hydrocarbons)

	Fuel Ratio	
	From	To
Hard, dry anthracite.....	100	12
Semi-anthracite.....	12	8
Semi-bituminous.....	8	5
Bituminous.....	5	0

(This classification has been widely used in North America, but obviously it does not distinguish lignites, cannels, splints or a score of coals recognized by trade names from one another. It does not distinguish between the high-volatile and low-volatile bituminous coals nor between the low-moisture coals of the Pittsburgh region and the high-moisture coals of the Illinois region which differ greatly in heating value. It is followed in the classification here proposed as far as it applies.)

Regnault, extended by Grüner, revised by Bone (dry, ashless fuel)

	Per Cent Fixed Carbon Below 55	Per Cent Volatile Matter Above 45
(A) Lignites (non-caking).....		
(B) Bituminous	1. non-caking, long-flame..... 55-60	45-40
	2. caking, long-flame..... 60-68	40-32
	3. hard-caking..... 68-74	32-26
	4. hard-caking, short-flame..... 74-82	26-18
(B.C.) Semi-bituminous, non-caking, short-flame.....	80-85	20-15
(C) Anthracites	steam-raising..... 85-92	15- 8
	domestic..... 92 or more	Below 8

Wedding (Dry, ashless fuel)*

	Per Cent of Volatiles
(1) Lean anthracite coals.....	5.0 to 10.0
(2) Sintering coals (old) poor in gas.....	10.0 to 15.5
(3) Caking coals (old) poor in gas.....	15.5 to 33.3
(4) Caking coals (recent) rich in gas.....	33.3 to 40.0
(5) Sintering coals (recent) rich in gas.....	40.0 to 44.4
(6) Sand coals (recent) rich in gas.....	44.4

* Grundriss der Eisen huttenkunde.

nine types, based largely on physical differences in plant composition and texture.

Besides practical classifications, of which examples have been given, many attempts have been made to classify coals by using the ratios of certain elements obtained by ultimate analysis. None of these classifications has gained practical recognition here or abroad.

During the war coals were pooled for more efficient handling. As no practical accepted classification existed covering the need, groups of mines producing coal of similar type and grade were grouped in numbered pools. Since then many analyses of the coals have been made, and average analyses of the coals in the several pools have been published by Dr. H. M. Payne. These reveal the differences that practical coal men deemed worthy of being distinguished by pool numbers. They also reveal the coal man's interpretation of "low-volatile," "medium-volatile," and "high-volatile."

The time seems ripe, therefore, to take advantage of all the work that experience has shown to be of real value to the coal producer and coal user, and from it prepare and adopt a classification of coals.

Coals differ, broadly speaking, in three ways:

(1) In type, as cannel, splint or caking coals, due to differences in origin, involving differences of plant material and conditions of deposition.

(2) In grade, as low-ash coals; high-sulphur coals, due to differences in quantity and character of mineral

matter contained in the plant material or washed in during the deposition of the vegetal material, or carried in later by circulating waters.

(3) In class or rank, as anthracite, low-volatile bituminous, high-volatile bituminous, lignite. Differences in class or rank are caused by pressure, heat and folding of the original deposits, resulting in progressive distillation of the volatile constituents of the original material (including inherent water) and an increased ratio of uncombined or "fixed" carbon. At the same time the original body of vegetal material underwent physical changes in texture, structure, hardness, weight, fracture and in other ways.

Any adequate classification of the several kinds of coal must recognize the three foregoing fundamental differences in type, grade and class; it must consist of three parts, one of which indicates the type, another the grade, another the class.

Types of Coal—Three general types based on origin are given in Table II:

TABLE II—THE THREE TYPES OF COAL

- (1) Common, "fat," resinous or "bituminous" coals.
- (2) Splint or "dry" coals.
- (3) Cannel or canneloid coals.

Coals of the "common" type are derived from various kinds of plant life that lived in the ages of coal. These coals were almost certainly derived from peat bogs where the plants grew and where the coal is found today. This type is commonly laminated with irregular bright and dull streaks. The bright streaks, usually lenticular, consist of woody materials altered to jet; the dull streaks are a mixture of woody and other plant fragments, spores and spore cases broken down into a nearly structureless mass. The Pittsburgh bed in the Pittsburgh region is typical of this type of coal. It is a caking coal in the middle stages of the change from peat to anthracite.

Cannel coal, in contrast, is believed to be a water-laid deposit composed mainly of plant spores and of plant detritus washed into open water within the swamps. Fish remains are occasionally found with the plant material. Cannel coal is easily distinguished from the common type of coal by its massive, non-laminated structure, its velvety luster and conchoidal fracture as well as in many other ways. It is characteristically a non-caking, long-flame coal high in volatile matter. True cannel coal has more volatile matter than fixed carbon.

EVEN SPLINT COALS VARY IN CHARACTER

Splint coals are of two types; one is dull gray and massive, apparently consisting entirely of plant detritus identical to that in the dull layers of common coal. Cross-sections of the other type reveal many thin layers of bright and dull coal. Splitting along the dull layers reveals a surface of "charcoal," "mother-of-coal," or "coal rash."

These charcoal-like layers consist of almost pure carbon and are thought to represent the dried surface of the swamp. This drying of the surface appears to have occurred with great regularity in some coals and suggests seasonal change. Both types of splint coal are distinguished by a splintery fracture like that of wood. Both kinds are non-caking. Cannel coals are characteristically low in moisture and splint coals are high, probably because the spongy charcoal layers absorb moisture.

Classes of Coal.—All three of these coal types are

found in various stages of alteration from their original condition as a bog deposit to anthracite or graphite. There are canneloid lignites and canneloid anthracites as well as bituminous cannel. For classification naturally they may form three parallel series. It should therefore be possible to plan one series showing the stages of the change of the common type and apply the same names to the other types. Attention may be confined for the present to the common type of coal.

The first step in converting peat to coal is bacterial action which may partially or entirely obliterate the plant structure. Then follows compression by overlying subsequent deposits. Later, horizontal pressure may throw the originally horizontal deposit into folds, induce vertical joints and fracturing, and drive off part of the "moisture" and more or less of the volatile hydrocarbons of the original deposit.

If this horizontal pressure becomes great enough the moisture is nearly all driven off and the volatile matter reduced to 20 per cent or less. The coal may be squeezed until it fractures easily along innumerable vertical planes. This is the stage of the "low-volatile" or smokeless coals. Still greater pressure may reverse the fracturing tendency and cement the bed into a hard anthracite.

Locally, as in Rhode Island, the pressure has been so great that the coal bed flowed like putty. Practically all the volatile matter and moisture was lost and only the fixed carbon left in the form of graphite. Similar changes may be brought about by the intrusion of hot igneous rock.

The ash of the coal is mainly an accidental ingredient varying in the same bed from point to point or even in the same mine. It must be either disregarded in any acceptable classification or the coal reduced to a "standard" proportion of ash.

As ashless coal does not exist in nature, and as "ash-free" analyses give slightly higher ratios of the other ingredients, a classification based on a selected "standard" amount of ash probably will be more useful, require less explanation, and eliminate much mental calculation in interpreting ordinary analyses.

The average of a large number of samples of "seaboard" coal suggests the use of 7 per cent ash for this purpose. There remains, according to the ordinary proximate analysis, the moisture, volatile combustible matter and fixed carbon.

SOME VOLATILE MATTER NOT COMBUSTIBLE

The alteration process involves the gradual chemical elimination of the moisture and volatile matter, resulting in an increased proportion of fixed carbon. Recent studies have shown that: (1) A part of the so-called volatile matter consists of hydrogen and oxygen in the proportion of water and having all the practical effect of water in burning—the so-called "inert volatile matter." (2) Under defined conditions the moisture of a coal is characteristic of the coal. It has been found that after dried coal is submitted to a moist atmosphere at various temperatures and vapor pressures a definite quantity of moisture will be re-absorbed and retained.

Where it is necessary to determine the amount of moisture with extreme accuracy, the suggested "standard moisture" of any coal should be its moisture content at a temperature of 68 deg. F. and an aqueous-vapor pressure of 15 mm. of mercury. The coal then may be considered to consist of fixed carbon, volatiles

TABLE III—NEW CLASSIFICATION OF COAL ACCORDING TO ITS CARBON CONTENT

Descriptive Names	Suggested Short Names	Suggested Code Names	Range of Fixed Carbon, per cent* (incl.)	Moisture	Volatiles Matter	Fixed Carbon	Ash	Fuel Ratio	Suggested Technical Names
Anthracite or hard anthracite.....	Anthracite	Coal 88	83 or more	3	2.88	7.12	+		Anthracite
Freeburning, soft or semi-anthracite....	Semi-anthracite	Coal 82	80-82	3	7.83	7.12	-8		Semi-anthracite
Semi-bituminous "Admiralty".....	Loervol	Coal 77	74-79	3	13.77	7.8-5			Loervolite
Low-volatile smokeless bunker.....	Lovol	Coal 70	65-73	3	20.70	7.5-3			Lovolite
Medium-volatile coking byproduct.....	Midvol	Coal 63	60-66	3	27.63	7.3-2			Midvolite
High-volatile gas.....	Hivol	Coal 56	53-59	3	34.56	7.2-			Hivolite
High-volatile.....	Hiervol	Coal 49	46-52	6	38.49	7.2-			Hiervolite
High-volatile sub-bituminous.....	Moistvol	Coal 42	39-45	15	36.42	7.2-			Moistvolite
Sub-bituminous.....	Himoist	Coal 35	32-38	25	33.35	7.2-			Himoistite
Lignite.....	Lignite	Coal 28	25-31	40	25.28	7.2-			Lignite

* Based on 7 per cent ash and moisture determination after coal has been subjected to a temperature of 68 deg. F., and 15 mm. of mercury-vapor pressure.

(including moisture) and 7 per cent ash, making together 100 per cent of the coal. In the process of change from peat to anthracite the volatile decrease in ratio and the fixed carbon progressively increases.

Coal may be classified by either the decreasing quantity of volatiles or by the increasing quantity of fixed carbon. The use of volatiles may lead to confusion because, though in many early coal analyses the moisture and the volatile hydrocarbons were not separated, for many years "volatile matter" has been used to designate the volatile matter left after the drying of the coal at a temperature of 110 deg. C. or 230 deg. F. Less confusion will result if classification depends on the percentage of fixed carbon.

I propose to classify all coals of the common or "bituminous" variety on the basis of the percentage of fixed carbon in a "standard classification analysis," which may be defined as an analysis recalculated (if necessary) to 7 per cent ash, and one in which (if necessary) moisture has been determined at a temperature of 68 deg. F. and a pressure of 15 mm. of mercury vapor. Ordinarily the recalculation or use of "standard" conditions for moisture determination will not be necessary, because the range in percentage of fixed carbon is wide enough to allow some variation from standard ash or moisture. Recalculation is necessary only where the fixed carbon of ordinary analysis is very close to the line between two classes.

In the above table are given, first, some of the descriptive names now in use; second, suggested brief names, mainly new, which are presented and defined; third, a list of code names (in place of pool numbers); fourth, the range of the percentage of fixed carbon for each class; fifth, an average analysis for each class; sixth, the fuel ratios of each class; seventh, suggested technical names terminating in *ite* to correspond with graphite, anthracite, lignite.

CLASSIFICATION BY PER CENT OF FIXED CARBON

The names and limiting factors have been reduced to the simplest terms. The key to the scheme is the number seven. The code names, except for anthracite, are multiples of seven, as 77, 70, 63. Each of the numbers is in the middle of the range of fixed carbon for its class; thus, coal 70 covers coals having between 67 and 73 per cent of fixed carbon. In other words, the class of a coal will be expressed by the multiple of seven nearest to the fixed carbon of a proximate an-

alysis, provided that the ash is near 7 per cent. For example, a coal carrying 62 per cent of fixed carbon and 6 per cent of ash belongs in class coal 63. If the percentage of fixed carbon is nearly halfway between two multiples of seven (say 59.6) and the ash is very high or very low, it may be necessary to recalculate the percentage of fixed carbon to a 7 per-cent ash basis, in order to be sure of the classification. Usually a glance at the percentage of ash will show whether the recalculation would raise or lower the percentage of fixed carbon and may save the time of an actual calculation.

TABLE IV—EQUIVALENTS OF POOL NUMBERS IN NEW CLASSIFICATION

Short Name	Code Name	Pool Numbers
Loervol	Coal 77	1, 2, 3, 44, 54, 64, 84.
Lovol	Coal 70	4, 9, 20, 42, 71.
Midvol	Coal 63	5, 7, 8, 10, 11, 12, 14, 43, 53, 63.
Hivol	Coal 56	6, 15, 18, 21, 30, 31, 32, 33, 34, 35, 37, 38, 39, 40, 41, 44, 45, 15, 53, 54, 56, 60, 61, 62, 63, 64.

Accepting the average analysis of coal in each tide-water pool as published by Henry M. Payne in *Coal Age* for March 17, 1921, the coals are approximately classed as in Table IV.

The above relationships are not guaranteed to be true of all coal in each of the several pools, as a single average analysis has been used for each pool; some of the analyses are just within the limits of the claim.

Coal Grading.—By the grade of coal is commonly meant the percentage of ash. It is proposed that where ash alone is involved the letters A, B, C, D, be added to the code name to express four grades, for which the following limits are proposed: A (superior or excellent), below 8 per cent of ash; B (good), 8-12 per cent of ash; C (fair), 12-16 per cent of ash; D (poor), above 16 per cent of ash. Thus "coal 63-A" is a medium-volatile bituminous coal having less than 8 per cent of ash; "coal 42-C" is a high-moisture bituminous coal carrying between 12 and 16 per cent of ash.

In most transactions involving coal the ash is the only element considered in grading. For some uses, however, it is desirable or necessary, to consider either or both the percentage of sulphur and the fusing point of the ash. To cover these in the code it is proposed to use a second and third set of letters A to D to designate superior, good, fair and poor quality in the coal as regards those factors. Thus "coal 63" is a medium-volatile (or midvol) coal, of any grade. "Coal 63-B" is the same coal with the limits of ash designated. "Coal 63-BA" is the same coal with the ash and sulphur classified. "Coal 63-BAA" defines the content of ash and sulphur and the fusing point of the ash. Table V gives the minimum and maximum limits of each letter in each grade.

Grading Anthracite.—The grading of anthracite is a subject by itself. Grading usually has been on the basis of the percentage of slate and bone observable to the eye. In practice, 100 lb. of coal is taken from a car, drawing from not less than three places in the car, spread out and the slate and bone separated and weighed. During the war the Fuel Administration set the limits on anthracite of different sizes as specified in Table VI.

After a study of a large number of car inspection tests I propose the following limits for grading anthracite according to visible slate and bone contained. Secretary Walsh, of the State Department of Mines of Pennsylvania has co-operated in this study.

It must be remembered that the slate and bone is in addition to the ash in the coal itself. On the other hand the bone coal may have as high as 70 per cent of coal matter. It must also be remembered that in the alteration from bituminous coal to anthracite the ash increases in the same ratio as the fixed carbon. A bituminous coal having 56 per cent fixed carbon and 8 per cent of ash, if altered to an anthracite having 84 per cent of fixed carbon, should have 12 per cent of ash. It is therefore hardly fair to expect anthracite to be graded on the same low percentage of ash as bituminous coal.

Considering the cost of cleaning and sizing anthracite and that steam sizes may sell at the mine at one-fourth the cost of mining and preparing, it is not to be expected that the steam sizes will be cleaned with the same care as household sizes while they sell at present low prices.

Code Designation of Cannel and Other Coals.—The table of classes given in an earlier paragraph treats of the common type of caking bituminous coals and anthracites derived from that type, which may be taken as "standard" type coal. Letters may be added to the class name to express other types of coal as follows: "K" for canneloid coals or "semi-cannel coals" of any class; "KK" for cannel coals (coals in which the percentage of volatile matter exceeds the percentage of fixed carbon—or the fuel ratio is less than 1); "KKK" for boghead coals (in which the fuel ratio is less than one-half); "KKKK" for Torbanite or oil shale.* Sp designates a splint coal; X, a sub-bituminous coal; L, lignites. Thus "Coal 63 KBAA" is a canneloid, medium volatile coal having between 8 and 12 per cent ash, less than 1 per cent sulphur, and a fusing temperature of ash above 2,600 deg. F.

COAL READILY CAN BE PLACED IN RIGHT CLASS

All coals can be classified by this plan as closely as ninety-nine out of one hundred users need, with little expense for chemical analyses, as the "class" is determined by the percentage of fixed carbon and ash alone. If the percentage of fixed carbon is close to the limits of the class and the ash far above or below 7 per cent, recalculation of the fixed carbon may be necessary to determine the definite class to which the coal belongs. To recalculate, divide the percentage of fixed carbon by 1 less the algebraic difference between .07 and the percentage of ash.

Practical Application.—The results of the application of this classification to coals of many states will be interesting. The following notes apply to some of the better-known coal fields of the United States.

Pennsylvania.—Anthracite is cleaned as "anthracite" or "coal 88"; the grade is commonly BAA for large sizes. The coal of the western ends of the Western, Middle, Southern and Bernice fields is semi-anthracite or "coal 82."

At a few places in Huntington, Bedford, Cambria and Somerset counties the coal is of a "Loervol," or

TABLE V—GRADE OF COAL EXPRESSED BY LETTERS

Grade	First Letter Ash Per Cent	Second Letter Sulphur Per Cent	Third Letter Fusing Point of Ash in Deg. Fahr.
"Superior"	A = less than 8	A = less than 1	A = over 2,600
"Good"	B = 8 to 12	B = 1 to 2	B = 2,600 to 2,300
"Fair"	C = 12 to 16	C = 2 to 5	C = 2,300 to 2,000
"Poor"	D = 16 or more	D = 5 or more	D = less than 2,000

*For detailed description of cannel coal see U. S. Geological Survey. Bulletin 659.

TABLE VI—WAR-TIME LIMITS ON IMPURITIES IN ANTHRACITE

"coal 77," class (semi-bituminous). In general, however, the coal of the eastern or mountain counties of the bituminous field is of "Lovel," or "coal 70," type, grade A or B. The coal of Indiana County and eastern Westmoreland and Fayette counties is "Midvol," or "coal 63," class, and all of the coal in the western and northwestern counties is of "Hivol," or "coal 56," class.

Maryland.—Most of the coal of Maryland is of "Lovel," or "coal 70," class.

Virginia and West Virginia.—The coal of the Pocahontas district in Virginia and West Virginia is "Lovel," or "coal 70," class, grading rapidly into "Hivol," or "coal 56," in Russell and Wise counties, Virginia, and in western Fayette and Kanawha counties of West Virginia. In Harrison and other western counties of West Virginia the coal is of "Hiervol," or "coal 49," class.

Ohio.—The coals in the eastern part of the Ohio coal field are of "Hivol," or "coal 56," class, and of "Hiervol," or "coal 49," class in the western part.

Eastern Kentucky and Tennessee.—Most of the coal in eastern Kentucky and Tennessee is in "Hivol," or "coal 56," class, but some "Hiervol," or "coal 49," class coal is present.

Indiana, Western Kentucky, and Illinois.—The coal of the eastern interior region is, in part, "Hiervol," or "coal 49," class, notably in the Ohio River areas and, in part, of "Moistvol," or "coal 42," class. The coal of the northern and western parts of Illinois particularly is of the "Moistvol" class, the percentage of fixed carbon decreasing from the southwest corner to the northwest corner of the state.

Missouri and Iowa.—The coals of Missouri and Iowa belong to "Hiervol" and "Moistvol" classes, or "coals 49 and 42," except in Barton County, Missouri, where the coal is of "Hivol," or "coal 56," class.

Georgia and Alabama.—Georgia has some coal of "Lovel," or "coal 70," class. The coal of Alabama ranges from "Midvol," or "coal 63," in the east to "Hivol," or "coal 56," to "Hiervol," or "coal 49," in the west.

Arkansas.—Some of the coal in the Shinn basin, Pope County, is of semi-anthracite, or "coal 82," class. The coal of Johnson County is mainly "Loervol" class, or semi-bituminous coal ("coal 77"). The coal of the western counties is in the "Lovel," or "coal 70," class. The lignite of Lester County is a cannelloid lignite or, "coal 28-KK."

Texas.—The lignites of Texas are, in part, cannelloid (28-KK), and in part the ordinary type ("coal 28"). The bituminous coals of the north central part and of

the Eagle Pass region are of "Hivol" ("coal 56") class, and "Hiervol" ("coal 49") class. The coal of the Laredo area is a bedded cannel of "coal 35" and "coal 42" classes.

Oklahoma.—The coal near the eastern Arkansas line is of "Lovel," or "coal 70," class. Westward the coal changes through the several classes to "Hiervol," or "coal 49," class, as in Coal County.

Kansas.—The coal of Kansas is of "Hivol" and "Hiervol" classes ("coals 56 and 49").

Western States.—The coals of the Rocky Mountain and other Western states are extremely variable from field to field, ranging within short distances from anthracite to lignite.

Book Reviews

Pros and Cons for Coal Debaters

GOVERNMENT Ownership of Coal Mines," by Julia W. Johnsen, is an excellent compilation of 392 5x7-in pages, published by the H. W. Wilson Co., New York, as one of the series of the University Debaters' Annual. The entire book consists of a collection of papers, with the source given in each instance, on the aspect of coal as a public resource and considerations for and against the government entering upon a more direct trusteeship in the immediate interest of the people as against private ownership. Both the articles selected and their references have been classified as general, affirmative and negative, and there also is a brief. A separate section is given to government control or regulation of coal prices.

To all appearances the compiler has been impartial in her selection of material, for we find Herbert Hoover and J. D. A. Morrow alongside of John Brophy and Louis Bloch. Even W. Jett Lauck and John Spargo are drawn upon. The author also has drawn upon British sources for arguments pro and con on nationalization, where the matter has been more thoroughly argued out than in this country.

The book will prove extremely useful to the multitude of high schools and colleges that are now and have for several years been debating the subject of the nationalization of coal mines. This is the first book, we believe, that puts into their hands a compact summary of articles containing material possibly useful in preparing for such debates. From the number of inquiries that have come to the desk of the editor of *Coal Age* in the last few years, asking for just this kind of material, it is quite certain that this book will get a wide distribution.

Training of Oxyacetylene Welders

IN THE form of an outline of a course for the training of oxyacetylene welders the American Welding Society has just issued a report of its committee on welding. For the employer the text includes a discussion of the qualifications that a candidate for instruction should possess. There also is included fundamentals in gas welding and a description of various types of welding jobs. Copies of the report may be obtained from the American Welding Society, 29 West 39th Street, New York City.

Why It Pays to Keep Electrical Equipment At Coal Mines in Repair

Production Delays Usually Due To Breakdowns Which Would Not Occur If Equipment Were Given Prompt and Careful Attention—Advantages of Training Motormen and Hoist Operators to Become Electricians

By M. S. BEDDOW
Scranton, Pa.

THE hurried attention usually given to electrical mine equipment during a breakdown naturally brings forth the question: "Why not a little foresight before the breakdown instead of so much hindsight after the delay occurs?" Too often the energy of all concerned in the production of coal is used up in an all too careless a manner when a mine locomotive, for instance, is on the repair pit and the movement of coal to the foot of the shaft is temporarily stopped as a consequence. Repairs made during the delay usually are not of a permanent nature, serving only to keep the locomotive in operation for the remainder of the day.

Important parts of the locomotive sometimes are disturbed in making a hasty repair, and are not readjusted as they should be by regular overhauling. Electricians so skilled in their trade as to be considered experts do careless things in a time of excitement such as is brought upon them during a breakdown of important machinery. The old saying "What is worth doing at all is worth doing well" should have a peculiar significance to the mine electrician.

A mine locomotive can be made just as efficient or inefficient as those in direct charge of it are desirous of making it. Nothing better satisfies an electrician or mine foreman than a perfectly operating piece of equipment. The grinding of bad fitting gears, the vicious flashing of a commutator due to ill fitting brushes, the shrill squeaking of a trolley wheel crying for oil and a whole locomotive going to pieces due to double-flanged wheels pounding over latches and frogs are as so many stabs in the back to the man who really and truly cares.

Fig. 1—Trolley Locomotive Complete with Cable Reel

This popular type of locomotive used in gathering work weighs 8 tons and therefore is capable of handling semi-main-haulage loads. The reel permits its use in gathering work. If every detail of a locomotive were maintained in as good condition as when new there would be fewer transportation delays and accidents.

General observation over a period of twenty years has convinced me that a smooth-working locomotive will not only bring more coal to the foot of the shaft in a given time but will tend to build up the morale of the whole operating force. A smooth working locomotive rides easier, and a motorman compelled to ride it all day probably can tell best just what this means. That this is so is obvious from the fact that it is not difficult to keep an operator on a locomotive which rides easily, whereas it is almost an impossibility to get a regular runner for the other kind. It is no difficult matter to keep a locomotive in good condition when every detail is promptly attended to and repaired.

Badly fitting gears and drive pinions need not be in this condition if proper measures are taken to see that they are brought into perfect alignment when first installed and are carefully maintained by having the axle bearings fit as snugly as possible with no great amount of wear at the bearing surface and shoulder, so that there will be little opportunity for the motor to slide sidewise on the drive-wheel axle. Axle bearings, or linings, as they are familiarly called, should be removed when it is noticed that they are worn sufficiently to allow the pinion and gear to get out of perfect alignment, for it is this loss of metal which allows the uneven wear across the face of the teeth almost invariably noticed on all discarded gears and pinions.

KEEP BEARINGS IN PROPER FIT

Insufficient hub liners or badly worn journal boxes serve only to allow the whole locomotive frame to move from its natural position; then there can be no true alignment of pinions and gears. Worn journal boxes are not easily prevented, but there is no getting away from the fact that hub liners are made for the purpose of taking up this wear, thus preventing the side motion referred to above. In this respect it is only necessary to take notice of how neatly this point is taken care of when a locomotive is first received from the manufacturer. If the general condition of the locomotive were taken as a pattern at this time and an honest effort put forth to keep it as near this condition as possible, what a splendid difference would be noticed in electric mine-locomotive operation!

The gear wheel, another important feature of a locomotive, should be put on the axle before the wheels are put under the locomotive and great care should be taken that the bore of the gear fits snugly down on all points of the axle. Due to the fact that the same axle is used over and over again, the worn wheels being pressed off and new ones pressed on at the foundry, considerable wear is found at the gear fit as well as at the axle lining fit, and sometimes an effort is made to install a gear over this worn portion. If a little more time is taken and extra care used a very serviceable job is

Fig. 2—Repairing the Motor

Whenever it becomes necessary to repair the motor all parts should be carefully removed and replaced. Pinion puller, ball-race pullers, etc., are essential and should be on hand; otherwise the parts will be hammered off and probably broken.

sometimes done, but it is questionable whether it pays to install an axle which necessitates this precaution being taken. In late years well-equipped foundries, by the use of welding equipment, fill in these low spots and then machine off the axle to the original gear-wheel fit. Axles are often installed upon which this has not been done, however, and the electrician is soon confronted with a loose gear wheel, which does considerable damage to the entire locomotive before it is attended to.

Special emphasis should be placed upon the great need for having in the locomotive pit at all times an extra pair of wheels upon which the gear wheel has been fitted with the greatest care. The reason for this is so that there will then be no need of a hurried job when it becomes necessary to change wheels on the locomotive during the day. Quite often a pair of badly worn wheels will break off a piece of a wheel flange 10 or 12 in. long and the locomotive must immediately be taken out of service. If there is not a spare set of wheels ready, completely fitted up with a gear wheel, it will be necessary to place the gears on hurriedly, and nine times out of ten it is done in an unsatisfactory manner.

The function of the axle lining is to hold the motor so that the pinion and gear will mesh properly. Any great amount of wear will prevent this. Just as properly lined up journal boxes prevent undue side motion, so do neatly fitting axle linings prevent the gear and pinion from meshing improperly. Nothing short of false ideas of economy will prompt the electrician to deliberately allow axle liners to remain in service when they are worn to the point where the pinion is allowed to pull away from the gear. The back lash which occurs results in the destruction of both gear and pinion, to say nothing of the unnecessary damage to the rest of the equipment. The habbitted type liner used on some of the earlier locomotives can be refilled and bored to the proper size for use again; the brass ones usually are turned in with the old brass scrap.

A locomotive which is not given regular attention will soon become a hindrance rather than a help to transportation. So many things contribute to keeping

it in or out of good operating condition that it is difficult to put one's finger on any particular point of most frequent trouble. However, it is doubtful whether any other one thing will aid in keeping a locomotive in service so much as a properly working controller. Here we have what has been aptly termed the brains of the locomotive with many working parts which will make or break its proper functioning. From this point the motors are made to work in series or parallel, depending upon the severity of the task put before them; from here proper steps are taken for cutting just enough resistance in or out of the circuit so that the right amount of current is allowed to flow to the motors in order that they may perform a certain duty.

Possibly no other part of the locomotive is so essential to its proper performance, and no other part is so badly abused and neglected. A network of wires leading to a score of different places, each with its separate duty to perform, offers an opening for just that many cases of trouble, any one of which might result in so seriously crippling the locomotive that it will have to be taken out of service temporarily at least. The controllers as used on mine locomotives consist generally of four important parts, viz., main cylinder, reverse cylinder, blow-out coil and the swinging pole piece, on which is the arc deflector with its division plates.

Going in by way of the blow-out coil the power is led through to the main cylinder, from which point it makes its way to the proper resistance box and thence to the motors by way of the reverse cylinder. As this entire path up to the point where the reverse cylinder is passed is all in series, it does not require much imagination to see that it needs only one open circuit, indeed a high resistance at any one of these innumerable contacts, to stall the locomotive.

Wiping contacts, such as are found in all drum controllers, have the disadvantage that they demand a certain amount of pressure and sufficient wearing surface. The path from a lead wire to a finger and through this to a wiping contact down through the segment on the cylinder must be as near a solid as it is possible to make it, and the very truth that it is not a solid should make the repairman doubly certain that all terminals

Fig. 3—The Locomotive Motor

The distance between the center line of the armature and driving axle is very important and must be maintained very accurately because it establishes the mesh of the driving gear and pinion. Note that the brasses are removable for replacement when worn.

are soldered properly, fingers screwed tightly to finger bases; finger bases in turn bolted fast to the main finger board, and last, but not least, the under side of the segment, which carries the power from the finger to the main cylinder, must be free of foreign substances which will creep in if it is not held tight to the block on the cylinder by the steel studs provided for this purpose.

A loose segment will soon gather a scale on its under side, which together with the loose segment will set up an almost infinite resistance to the passage of power and gradually develop heat which will pass back along the finger to the fingerboard, in time destroying the latter and making it unfit for further holding the finger solidly against the base. Much of the trouble experienced with controllers used on mine locomotives comes from burned finger boards, eaten away at the point where the finger base is fastened to it. Without a single exception this particular trouble can be attributed to either a loose segment or to the finger itself becoming loose and developing heat and passing it on to the board, with its consequent ill effects.

Very little trouble comes from the reverse cylinder and finger board, due no doubt to the fact that these are not subjected to the frequent strains that the main board and cylinder must bear. The contacts between the segments on the reverse cylinder and the reversing fingers are broken only when it is necessary to reverse the direction of travel of the locomotive, and this is so infrequent that little strain comes on the studs which hold the fingers in place. This pushing action, especially as it is repeated hundreds of times, as in the case of the main fingers, tends to loosen up the screws which hold the finger base to the board, and if these are not continually cared for the fingers become loose and lose their proper contact against the main segments.

It is due, possibly, to the character of the service it performs rather than to any extra care it receives that not much trouble is experienced with the reversing feature of the controller. The current handled is the same

as in the main cylinder, yet it seldom requires any attention aside from that care which comes through periodic inspections. A little lubricant thinly applied at certain intervals at the point of contact will prevent burning of both fingers and contacts and thus ward off loss of tension in these members which comes from too great an amount of heat. Precautionary measures such as these will help immeasurably in keeping the controller in service over a longer period of time than would be the case otherwise.

Probably no other person having to do with a mine locomotive in its day's run has a better opportunity than the motorman to observe its actions and apply first aid when it can do the most good. And it must be said to their credit that little escapes them, and many a serious breakdown has been prevented by quick action on their part. Indeed some of the most capable electricians in the anthracite mines have come up from the ranks of the motormen and hoist operators. And this is not to be wondered at, since these men learn by force of circumstance rather than from any other reason.

It is seldom that an electrician can be located immediately following trouble of any kind, as he may be in another part of the mine. For this reason the operators have learned to look for the trouble themselves while waiting for the repairman to arrive. In this way these men have acquired much skill, and it is not to be wondered at, therefore, that so many former motormen and hoist runners are now expert electricians and electricians' helpers.

FITTING MAN TO THE JOB

A number of years ago one of the larger coal-producing corporations required an applicant for a position as motorman or hoist runner to possess a certain amount of skill in the performance of his duties before being given the position. This knowledge consisted, aside from a general understanding of the duties of the job, of knowing just what to do in the event that something happened to put the machine out of commission. The questions asked were not intricate and the applicant had a general idea of what they would be beforehand, so that it was an easy matter for him to study up on the subjects before presenting himself for examination. The very fact that the prospective motorman or hoist runner was compelled to study at all in anticipation of what was to come served to make him a better man for the position, and, naturally enough, this plan resulted in the best man being chosen for the place.

During the examination the applicant was impressed with the fact that his position was first of all a responsible one, fraught with dangers that could be increased or lessened according as he performed his several duties. He was made to understand thoroughly, for instance, that a locomotive must always be provided with a proper grade of sand because it is extremely dangerous to try to operate on the heavy anthracite grades with empty sand boxes. The difference between series and parallel operation of the two motors was explained in detail and made so clear that the applicant received a thorough knowledge of why the series position must always be employed wherever it is possible. The harm which ensues from a general practice of the parallel position when a series coupling of the motors can be employed was made very plain in the beginning.

These men, it is scarcely necessary to say, become excellent electricians in after years at the finish of a

Fig. 4—Open View of Controller

From here every operation of the locomotive is regulated. Fingers and drum segments should be maintained in the best condition; otherwise heat will be generated at the contacts and not only burn the copper but the drum cylinder, thus requiring its complete renewal with the necessity of remounting each and every segment.

well-spent apprenticeship, during which time they were taught many useful things which served them well at a time when this knowledge was most needed. Running too much on resistance notches in the parallel position of the controller in order to get a certain decreased speed, when the same result could be brought about through full-series operation subjects the resistance panels to a terrific amount of heat, which in time buckles them and makes them unfit for further service. These and many other valuable points which come up from time to time are made plain to the applicant, and the usual result of this tutelage is a better motorman in the beginning and an excellent operator after a year or two of actual work on the job.

New Furnace Solves Problem of Burning Anthracite Dust

Difficulty in Ignition and Tendency to Clog Air Passages Overcome—Piles at Welsh Pits Hitherto Considered Only Waste Now Valuable

By C. H. S. TUPHOLME
London, England

ONE of the problems confronting engineers at the anthracite pits in South Wales is the generation of steam for use about the mine. In the bituminous field coal is burned either in lump or as slack in pulverized form. The difficulty of igniting anthracite even in lump form is well known, while to throw anthracite dust and fines on a fire is about as effective in smothering the fire as a load of sand. In natural-draught furnaces it is more than likely that the fines will put the fire out by choking the air passage, while if forced or induced draught is used the dust will be blown off the grate before it can be ignited. Consequently most of the attempts to burn these anthracite fines, which, by the way, have a heating value of over 13,000 B.t.u. per pound and only about 10 per cent ash, have failed. As a result there are many large piles of anthracite dust which are regarded only as a waste product.

GRATE HAS AIR BLADES

Lately, however, a special type of furnace has been developed which seems to have solved the problem and which gives excellent results when fired with anthracite dust. This furnace is commonly called the "Turbine," on account of the fact that the passage of air into it is almost exactly similar to the passage of steam on the blades of an impulse steam turbine.

The general construction of this furnace, which is set slightly closer to the boiler than the ordinary fire-bars, is shown in the accompanying illustrations. The furnace consists essentially of seven or eight longitudinal cast-iron trough bars, placed side by side according to the width necessary for the boiler, and a projection to protect the nozzles. The troughs are rounded at the bottom to a radius of 2 in., are 5 in. wide at the mouth and 6 in. at the firing surface, being shallower at the back than at the front. At each end the troughs are supported by lips which hook over bridges on the deadplate and on the bridge plate, as shown in the diagram, no drilling being necessary. The firebrick bridge is of the usual construction, but is combined with a second bridge shown in Fig. 1.

Located transversely in these troughs are a large number of cast-iron elements which slip into the trough, forming a composite grate. Each element rests on the upper edges of the trough and fits into the element in front and back. A length of trough containing forty-two of these elements constitutes a 6-ft. grate.

FREE AIR COURSES

Between each pair of elements is a small air space $\frac{1}{2}$ in. wide, so that the entire grate is a series of small air spaces, uniformly divided and communicating with the body of the troughs underneath. This construction insures an even distribution of air over the whole furnace.

The rear face of the blade of each casting is at an angle of 45 deg. to the top surface of the grate, while the forward face is at an angle of 60 deg. with the grate surface (see Fig. 4). The result of this design is that the $\frac{1}{2}$ -in. opening is maintained below in the form of an inclined and tapered air passage. The section in Fig. 1 shows that the lower edges of the sloping blades form a radius with the curved bottom of the trough, so that an air passage of approximately circular shape is provided. The area of this passage, through the angle at which the trough lies, narrows from front to rear so that as the air escapes into the furnace through one slot after another, the velocity of the air in the trough remains constant, which means also an even supply of air to every part of the furnace. This obviates the difficulty of most steam-jet furnaces, that the draught is unequal over the grate, because the air pressure diminishes toward the end of the bars.

The air combustion is supplied to each of the troughs by means of a steam jet through a gun-metal nozzle $\frac{3}{8}$ in. in diameter. The steam used is supplied by a $\frac{1}{2}$ -in. or $\frac{3}{4}$ -in. wrought-iron pipe from the boiler, as seen in Fig. 2, passing through the side flues so as to super-

This view shows how the air is introduced to the tubes by pipe connections to the boiler; (1) shows the location of a superheater wall box.

heat the steam, and along the front of the trough bars, so that one nozzle blows steam into each trough and forces a blast of air along the trough and through the $\frac{1}{8}$ -in. air spaces above into the furnace.

The steam-supply pipe is provided with a valve, the forced draught thus being under perfect regulation. A 10-lb. steam pressure indicated on the gage, Fig. 2, gives an air pressure in the troughs of 0.15-in. W.G.; at 20-lb., 0.25-in. W.G.; and at 35-lb. 0.35-in., W.G.; being, as already stated, constant throughout the whole length of the trough, so that the amount of air admitted is the same at all parts of the furnace.

Firing can be done by hand and the air supply regulated to burn more or less fuel as required. Any small amount of dust and fine ash that falls through the slots into the troughs is removed by means of a long-handled scoop inserted into each trough, but most of the ash falls between the two bridges. There is provided with the installation a cleaning door or flap operated by a chain from the front of the boiler, so that the ash and clinker falling between the two bridges can be raked out as required.

The small grate elements, as will be seen from the illustrations, are in the form of a V section lying in-

Fig. 3—Grates Which Do Not Distribute Air

Unless the grates are properly designed the air would not reach all the fuel, thus causing dead spots in the fire bed.

clined to meet the air blast—the name of the “Turbine” furnace is derived from the likeness of the arrangement to a steam turbine—the air enters the throat of the trough and passes through the furnace from between the elements.

When this furnace with the type of nozzle described was first used with fine anthracite it was found that it was possible to burn only a certain portion of the fuel charged so as to evaporate about 3,000 lb. of water per hour from a Lancashire boiler, using a limited air pressure of not over 0.6-in. W.G. under the bars. This, however, results in alternate black and bright patches, as seen in Fig. 3, the material on the bars being unburned, while any increase in the draught simply blew

the fuel off the bars. The solution of the problem is shown in Fig. 4. Instead of the unidirectional air slot between the elements, by means of a special design the air is spread in many directions. The design also is such that projection A overhangs into groove B, leaving an air space as shown in the section view at C. The projection A prevents any of the fine anthracite falling between the bars, and the air is so split up and subdivided that it has not sufficient strength to blow the material off the bars, but is strong enough to burn it

Fig. 4—Special Grate for Burning Fine Anthracite

Note that the air passageway is formed to distribute the air to burn all the fuel.

without any “dead” spots, whereas a straight slit, as in the ordinary bars, localizes the air too much and blows away the material.

This simple arrangement apparently has solved the problem of burning anthracite fines, and the furnace is now operating at one of the largest Welsh collieries with 1 in. W.G. or even lower, burning 20 to 30 lb. of anthracite per square foot of grate area per hour with a normal evaporation of over 6,500 lb. of water per hour from a standard 30x8-ft. boiler.

UP TO JUNE 30 LAST, coal and asphalt deposits in 93 tracts comprising 71,882 acres in the Choctaw and Chickasaw segregated areas, Mr. Merritt, of the Indian Bureau states, had been sold for \$1,975,934, leaving unsold deposits of 369,255 acres.

News Of the Industry

President Lewis Says Miners' Union Favors Loading Machines

But Will Not Talk Scale Until Loader Proves It Is Beyond Experimental Stage—Will Demand "Fair Share" of Benefits of Mechanical Loading

A settled plan for getting a continuance of the present agreement for a term of years continues to be the obvious program of the United Mine Workers of America. The end of the first week of their convention saw no important point brought out which was not apparent when the International assemblage opened in Indianapolis on the 22nd. The scale committee has not yet reported and may not bring in its message until its limit of time has arrived—on Friday—but the outcome is without much doubt.

The one interesting thing about the convention thus far is that the strength of the Lewis administration against the red and rebellious minority is proven. They failed to get the convention to reconsider the case of the Nova Scotia officers ousted from the union last summer for defiance of headquarters. They failed to get a resolution favoring the recognition of Soviet Russia and they failed in everything else except to get a long, loud voice. That has never been denied them.

The Lewis administration suffered its first real blow Tuesday, when the demand that Lewis be stripped of his power to appoint organizers swept the convention. The convention committee's report against the resolution for the election of organizers by the rank and file was rejected 760 to 734. Then 689 voted for a roll call on the question; only 570 votes were necessary. The roll call, which takes half a day, started immediately after noon. The drive to take appointive power away from Lewis has been growing throughout the convention and is backed not only by the so-called radical group but by many others. It is assumed that the strength shown against the administration on this matter will be about the same as will be shown in favor of demanding more wages later in the convention against President Lewis' program. Secretary of Labor Davis is to speak Wednesday against increased wages.

Take John L. Lewis' word for it, the miners' union favors underground loading machines. It is hastening rather than postponing, the inevitable day when loaders will revolutionize mining.

"The United Mine Workers favor the introduction of labor-saving machinery and always have favored it," said Mr. Lewis. "Anybody who says this is not so simply misrepresents the facts; that's all. We have always encouraged such machinery. The one thing the organization insists upon is that the mine workers be given their fair proportion of the benefits accruing from the use of machinery. The trouble has been that the operator has tried to keep for himself the entire benefit.

"This is exactly our position toward loading machines. The mine workers are co-operating all over the country in the development of loaders by permitting men to work the machines on day wage rates. This we are ready to do for any new loaders that are brought forward.

Important Convention Acts

Brought 1,500 delegates to Indianapolis from every union district for biennial meeting.

Displayed less defection than usual by the radical wing, which was firmly squelched by Lewis strength.

Reaffirmed original stand favoring nationalization of mines and railroads, but without positive action in the matter.

Declined to favor American recognition of Soviet Russia.

Declined to ally United Mine Workers, "an economic organization," with any united labor party because such a party would be purely political.

Supported the Lewis administration in its ouster of Nova Scotia district leaders charged with bolshevism and defiance of headquarters authority.

Referred to International Mining Convention at The Hague next summer the question of a world-wide strike of all labor to stop war.

Cleared Lewis of the radical charge that he "sold out" the union by ending the anthracite strike without getting the check-off.

"We recognize that mechanical loading is coming. It is going to revolutionize mining and the preparation of coal. The mine workers, however, cannot take part in negotiating a loader scale until loaders are developed to a point that will show definitely what these machines can do consistently. The experimentation has by no means progressed that far yet. Of course, it is known what certain machines will do for short periods under certain conditions, but this is only fragmentary information. Loaders are making progress in certain coal fields and I trust it will continue and will expand."

The convention opened quietly at 10 o'clock Jan. 22. No hoarse orators fought for the floor. Nobody hissed the chair. No maneuvering on the floor took place. There was hardly so much as applause even at the appearance of President Lewis, and during the international officers' reports. As reported in *Coal Age* of last week, President Lewis declared for a wage contract "for a period of years." Vice-President Philip Murray condemned bolshevism within the ranks and Secretary-Treasurer William Green showed the union to be clear of debt and to possess \$1,100,000 in bank. But nothing in the reports stirred up any enthusiasm. Only one or two gentlemen of the small radical opposition rose to protest Mr. Murray's sharp jabs and these were silenced by the president on the ground that debate could not begin until the committee on officers' report was made.

The various committees were appointed including the one on scale. The fact that Frank Farrington, Illinois president and one-time bitter enemy of Lewis, was made chairman of the committee on scale was indicative of the main harmony of the organization. John Hessler was made secretary. The resolutions committee was headed by Thomas Kennedy with Percy Tetlow secretary. Rules were made limiting speeches to 10 minutes, permitting a roll call on vote of 30 per cent of the delegates and forewarning belligerent speakers that a man can be expelled from the convention for refusal to abide by the rules of the session.

Samuel Gompers, president of the American Federation of Labor, in a verbose telegram, sent good wishes and urged the miners to support "super-power" plans as possible regularizers of working time in coal.

At the opening of the Wednesday session the report of President Lewis was accepted without argument. A

small storm broke over Vice-President Murray's report, however. Murray's condemnation of the efforts of the Progressive Miners roused much objection from the radical wing. He charged the Pittsburgh Coal Co.'s efforts to get wages reduced to the 1917 scale were behind the Axelton (Pa.) meeting of 500 men just after Thanksgiving, 1921, and the Dec. 4 meeting of 1,200 men soon after at Monongahela City, Pa. Defenders of the Progressives denied the meetings were held to reduce wages to the 1917 scale but merely to talk over what to do. Murray read the circular announcing the Monongahela City meeting, declaring no other interpretation could be placed upon it.

Defenders of the Progressives protested the ousting of the signers of the circular. P. T. Fagan and other union officers, however, condemned Tom Myerscough and the other principal leaders in the union defection in District 5.

The financial report was accepted after a brief discussion in which a hospital bill for Ellis Searles, union publicity chief was mentioned and in which John Watt, stormy petrel in Illinois, proposed that the Brotherhood of Locomotive Engineers' bank in Cleveland be condemned for refusing to lend the miners union money during the 1922 strike.

The first real fireworks of the convention were touched off during Wednesday afternoon, when the conclave got to work on the first of the 728 resolutions proposed from all over the country before the deadline 10 days before the convention opened. The resolutions ran the usual gamut from conservative to extreme radical points of view, including a number aimed directly at the embarrassment of the organization heads.

Clever work by the resolutions committee, headed by Chairman Thomas Kennedy and Secretary Percy Tetlow, staved off a good deal of war from the noisy but inferior minority. On the issue of recognition of Soviet Russia the committee reported in favor of recognition when that government recognized the right of every other people to shape their own destinies and when the Soviet Government fulfilled "honorable obligations." This came as a surprise since it did not condemn the proposal to recognize Russia, and therefore disarmed and rather disconcerted the radicals. So the committee's report was adopted without a dissenting voice.

In the same way the committee met the radical demand for affiliation of the United Mine Workers with a United Labor Party. In the resolution the committee substituted for the several that had been filed, it is "recognized that the formation of a Labor Party proper has passed the visionary stage and can be made a reality." yet it committed the United Mine Workers to co-operation with the progressive, legitimate political forces of labor and the organized farmers already in existence but

Miners' Union Is 34

On Jan. 25, in the midst of the International convention, at Indianapolis, the union became 34 years old. President Lewis, paying tribute to the "little group of organizers," said they "built better than they knew." The union has justified itself before the bar of public opinion in this country, he said. Mr. Lewis is ninth in the succession of presidents and he told the convention every one of his predecessors had retired with a feeling of sadness at the attacks always aimed at the president by sections of the union. Such is the lot, he said, of any United Mine Workers president.

held the union to be an economic organization for the increasing of miners' wages and the bettering of their condition and therefore should not affiliate with any purely political organization. This resolution, which included congratulations to the Laborites of England upon their winning control of their government, passed by a loud aye vote.

The real outburst came on the question of reinstating the ousted Nova Scotia district officers who long defied and embarrassed the International headquarters until they were dethroned by President Lewis last August. The administration's action finally was approved but not until much loud shouting had been uncorked and not until there had been a demand for a roll call with but 421 votes mustered for it out of the necessary 550.

The question of nationalization of mines, slated as another fighting topic, was skimmed over neatly. In place of the mass of nationalization resolutions the committee brought in one substitute which merely reaffirmed the past declaration of union policy favoring nationalization of both mines and railroads and the democratic management of all industry. The ayes had it loudly again.

Some Pennsylvanians and a few others were rousing in their demand that a new drive be made to organize the coke region and bewailed the fact that the union had quit the strike of 1922 without rescuing that region from the domination of union-fighting operators. Some said they were ashamed of the union for "deserting" the region. Secretary Green spoke in defence of the union's action only to draw a new fire. However, the 28 resolutions attacking the union's policy and calling for another coke-region war for organization, were replaced by one merely referring the matter to the executive board and urging it to continue the effort to organize the region 100 per cent. It passed easily.

Thus, all through the day, the Lewis administration was absolutely in control of the convention and rode the opposition down hard at every turn.

A delegate from the coke region,

James Chicolini, was refused a seat after a verbal battle by a vote of 840 to 250, on the ground that he is an officer of the Progressive International Committee, the radical wing of the union. This was followed by an attack on the administration for "railroading" reports of the resolutions committee. The committee's report against a resolution calling for the reading of all resolutions "as presented" was voted down.

The main reason for the outburst was the Wednesday action on the Nova Scotia matter. President Lewis also came in for a whack for not openly debating the charges made against him in Resolution 27 from local 155 of Weaver, Pa. It charged Lewis with having made statements that Frank Farrington, president of the Illinois Mine Workers, accepted \$100,000 in the strike period of 1922 to permit coal to be loaded out of the Herrin strip mine and that Farrington said Lewis accepted operators' money "for various reasons." The resolution demanded an investigation and "if these charges are true, these men are not fit to be members of our union, if the charges are not true a liar is not fit to be a member of the United Mine Workers, and that it is the sense of this convention that both men resign." The resolution committee merely found the charges "absolutely untrue" and the convention accepted this report.

The Brotherhood of Locomotive Engineers was bumped by Thomas Kennedy, who charged it with owning and operating non-union mines. This came up in defeating a resolution favoring affiliation of the mine workers with railroad workers. The committee's substitute resolution said everything possible had already been done to affiliate but it was futile because of the attitude of Brotherhood officers, but recommending that efforts continue to get a working understanding. Fred Mooney said he thought the time will never come when any affiliation can be made with the Brotherhoods—"the aristocracy of labor"—which never hesitate to desert the other railroad unions. Secretary Tetlow of the resolutions committee explained the Brotherhoods were not organized in a way that would permit affiliation with the miners.

The various resolutions to abolish war and vitriolically flaying capital for making wars for labor to fight were replaced by a substitute resolution abhorring the institution of war and referring the question of a world-wide strike in case of war to the International Mining Congress at the Prague next year. The final resolution was a subdued and sane document recognizing that this nation cannot disarm when other nations are "sounding their drums" and that the miners' union has no ability to cope with such a problem as world peace although the problem is worthy of the best union thought. John Wall and Freeman Tompson, radicals, of Illinois, made the usual capital-baiting speeches, but they were answered by such leaders as G. W.

Savage, of Ohio, who reminded the convention that capital, too, had given its sons and patriotically suffered its losses in war. The vote was a roaring "aye."

A resolution charging Lewis with "deliberately giving up the check-off" in the anthracite settlement was quashed after Tom Kennedy, of anthracite District 7, denied that allegation and explained how the miners got 10 per cent more wages, the universal 8-hour day with 12-hours pay, an equity clause in the contract and other benefits in such quantity that anthracite workers unanimously favored accepting even without the check-off.

Delegate Rooney, of District 1, an anthracite region, said the anthracite workers are able to take care of themselves and don't care a snap whether they ever get the check-off so long as they can keep their present solid union strength. Rinaldo Cappelini, another anthracite leader further emphasized the solidity of the union in hard-coal fields and its independence from influence outside that one group. Duncan MacDonald editor of a labor paper in Illinois, alleged author of an article against the check-off, was condemned as a non-union wolf in the union's sheepskin. He was defended by speakers of the radical group, but a demand was made that MacDonald be invited to the convention to defend himself. Philip Murray, temporarily presiding, would not permit a motion of invitation.

President Lewis, in his defence of his anthracite action, denied giving away anything belonging to the union but instead, got the men \$44,000,000 a year in increased wages. "The anthracite men," he said, "will tell you Lewis can sell them out any time for \$44,000,000."

In a tilt with John Watts, President Lewis denied he ever had written any letter charging Frank Farrington with receiving \$100,000 to permit the Herrin strip mine to run during the 1922 strike.

A resolution was adopted favoring restriction of immigration to as low a point as possible and the enforcement of the present immigration laws against smuggling of labor through Pacific and Canadian borders.

On Friday the convention declined to consider alliance with either the Amsterdam International or the Red International of Labor Unions, on the ground that both oppose labor and that the United Mine Workers "might as well ally with the United States Chamber of Commerce, the National Coal Association" or any other labor-fighting group. This action was taken over the heads of the radical wing without a "No." The convention demanded the repeal of such American laws as interfere with free speech and the freedom of assembly.

John P. White, former president of the union, addressed the convention, complimenting the present union administration.

So much noise in protest was made over the action of the convention in the Nova Scotia case Tuesday that at the

Safety by Radio

Radio as a life saver got attention from the United Mine Workers at the Indianapolis convention. Some locals wanted headquarters to set up a broadcasting station to counteract anti-labor broadcasting now going on. The convention's resolution, however, merely favored an investigation into the question of radio communication between top and bottom of mines. It was stated that within the last two weeks such communication has been established at a mine 1,000 ft. deep near Scranton, Pa.

beginning of the Friday afternoon session Vice-President Murray offered the opportunity to reopen the question. A mass meeting of 200 men the night before had damned President Lewis for "steam rolling" the convention in the Nova Scotia case. So debate on that case ran all afternoon and through Saturday forenoon before the convention once more supported the ouster from the union last summer of defiant Nova Scotian officers. The vote was overwhelming.

One of the thoroughly radical outbursts of the convention was a speech made Friday by John Watt. He condemned Lewis for publicly admitting there are too many miners in the industry, and declared the policy should be to reduce hours of labor so as to give everybody a job. He attacked the union for not stanchly and openly supporting "the brothers" who conducted the Herrin massacre of 1922, in which 21 non-union men were killed by an unidentified mob. Watt made sport of the union's public claim that the riot was due to communism.

"When good union men fought for unionism at Virden and Pana," said Watt, "they were heroes. Nobody called them communists and nobody should call the Williamson County men communists." Watt did not get a good reception with this bloody-shirt stuff. It appeared to send a shiver through the convention.

After beating the radicals on the Nova Scotian and other issues so many times, the administration thought best on Saturday to yield to the considerable demand for the reopening of the old Howat case and also the case of Myerscough, who had been booted out in Pennsylvania for leading the "Progressive Miners." This was announced Saturday for attention on Sunday by the grievance committee. The committee did not report on Monday but it was expected to report against reopening the two matters.

William Z. Foster, a recognized Red, came to Indianapolis to cause all the trouble he could. Saturday night he held a radical meeting at which he called President Lewis a liar in the statement that radicals in American labor had received millions from Russia. He urged the miners to "get rid

of the present reactionary leadership." Foster defended the Herrin massacre, saying that more such union acts would reduce non-unionism. The meeting was attended by the usual 250 or so rebels of the convention in a dark little back street hall. A squad of police was there but took no action.

After a long debate the administration suffered its first setback Monday morning at the hands of the radicals when the convention seated Nick Perovich, of Dowell, Ill., against the credentials committee's report and against the administration speakers. The man was fired from a mine for absenting himself from work for more than two days and therefore was ineligible for the convention. The administration favored standing by the contract with operators on the point of miners staying on the job, but the case was lost 668 to 611. The same radical group failed, however, to upset the committee in the case of John McGraw, of Kansas, who was finally denied his seat because he leased a mine and prepared it for operation during the 1922 strike.

A thousand dollars was appropriated to aid in the renewed defense of Tom Mooney and Warren K. Billings after Mrs. Mooney told the convention all about the famous San Francisco bombing for which Mooney is still in jail. She said new evidence has been dug up but it is secret. More community centers, athletic fields and playgrounds in mining communities were favored. Other resolutions opposed injunctions by courts and condemned interference in union affairs by such as Myerscough and Foster. An effort to change the constitution to permit members to join the Ku Klux Klan failed.

An effort to reduce the excess of miners in the industry by denying charter rights to all men except miners' sons and miners in newly organized districts was defeated without much discussion.

The entire convention stood silent for one minute Monday in sorrow for the dead of the Shanktown and John-son City disasters.

California Coal Dealers Deny Trade Commission Charge

The King Coal Co., as a company, and Frank J. Foran, as an individual and vice-president of the company, have issued an answer denying that they are members of the California Retail Dealers' Association or have been guilty of practices complained of by the Federal Trade Commission.

The complaint of the Trade Commission charged that uniform prices on coal were fixed by the respondents; that distribution of coal through channels other than those determined upon by the association was prevented and that co-operative purchasing associations were prevented from obtaining coal at wholesale under any conditions, causing obstruction in the sale and transportation of coal in interstate commerce.

32 Succumb in "Mysterious" Illinois Mine Blast

An explosion Friday afternoon, Jan. 25, in the East mine of the Crerar-Clinch Coal Co., Johnson City, Ill., caused the death of 32 miners and eight others are in a hospital suffering from injuries from which two are not expected to recover. Illinois mine authorities, the Coroner and officials of the coal company have joined in an effort to determine the cause of the explosion, which is believed to have resulted from the ignition of firedamp with a consequent explosion of dust.

At the coroner's inquest, officials of the coal company testified to the effect that the explosion in the mine was caused by gas being ignited by a miner's open carbide light. On the other hand, miners, all survivors of Williamson County's greatest mine disaster, blamed the company's officials for the explosion, because of their failure to observe certain safety rules, stress being laid upon the attempt to find the man responsible for the miners being sent into an entry in which gas said to have been formed by a squeeze or the loosening of coal.

H. L. Goodnow, superintendent of the mine, asserted in his testimony that the danger sign had been posted at the entrance to the squeeze and that he believed that the gas which had been formed by the squeeze was ignited by an open carbide light carried by one of the miners. G. I. Evans, mine examiner, employed by the coal company, told of having found the squeeze and having marked the entry as dangerous. His testimony as to precautions taken to keep the men out of the danger zone was supplemented by the statement of Floyd Howard, assistant mine manager, who said he believed Jesse Ford, face boss and one of the victims of the explosion, had ordered the men into the entry where the squeeze had been discovered. He admitted, however, that it was he who told one of the loaders to get his tools, but would not admit that he sent this man into the dangerous entry. He added that no gas had been found in the vicinity that morning. William Johnson, night boss manager, testified he was the man who had placed the danger sign on the entry.

Miners who were at work during the time of the explosion contradicted the testimony given by the officials of the company as to the presence of the danger sign. All agreed that no sign was to be observed at the entry when the men were ordered to tear up the track in the chamber in which the squeeze had been found. Louis Owens, a driver in the mine, told of unloading some cars several of which contained dry and dusty coal which caused such dust that he could hardly breathe. This testimony was given to show the contention of the miners' officials that the force of the explosion had been augmented by the presence of the dust which was ignited by the gas explosion.

How forceful the explosion was was brought out by the testimony of several men who had assisted in searching for the victims. Some of the men who had been working more than 300 ft. from the place of the explosion had been found dead, with their tools either in their hands or nearby their bodies. Miners also testified that several of the dead were men who had been sent into the abandoned chamber where the squeeze had been found, to tear up the tracks, and that these men carried open instead of safety lamps.

State Inspector Plum Lee was called on the stand to testify as to the condition of the mine as found by the State Commission on the day after the explosion. He asserted that the mine was found in good condition during this inspection.

The blast in McClintock mine at Johnson City, Ill., occurred at 2:45 p.m., Friday, just at the hour when the miners were preparing their shots. Permissible powder is used throughout the mine, according to E. C. Searles, of Chicago, general manager of the Crerar-Clinch Coal Co., operators of the mine. About 40 men were in the 11th northeast entry where the blast started, and the casualties were suffered entirely by the men in that entry, including Mine Manager McCullough and Driver Boss Ford, both killed.

William Griffith, Engineer And Geologist, Dies

William Griffiths, well-known mining engineer and geologist, died at his home in West Pittston, Pa., on Jan. 19, at the age of 69 years. Born Jan. 12, 1855, he was a member of the class of '76 of Lehigh University being graduated as a civil engineer. In 1878 he obtained a position with the Union Pacific R.R. and surveyed and supervised the construction of railroads in Nebraska, Idaho, Montana, Utah and Colorado.

Two years later he returned East and became division engineer with the Lehigh Valley Railroad Co. In 1880 he became assistant geologist on the Second Geographical Survey of Pennsylvania and supervised the mapping of the Schuylkill, Lehigh and Bernice coal measures. He had charge of the completion of the geological survey of the Lackawanna and Wyoming coal fields in 1887 and then opened an office at Scranton as a consulting mining engineer and geologist.

Mr. Griffith investigated and rendered a report on the anthracite deposits of northern Peru in 1897, and from 1906 to 1908 he examined and reported on the coal resources of the Matanuska Valley, in Alaska. With Eli T. Conner, another well-known engineer, Mr. Griffith was appointed by the City of Scranton to investigate the risks to which that city was exposed by the extensive mining work being carried on beneath it and made an extensive report which later was published by the U. S. Bureau of Mines.

He was a frequent contributor to technical magazines, his last article in *Coal Age* appearing in the issue of June 7, 1923.

Mr. Griffith was a member of the American Institute of Mining and Metallurgical Engineers, the Mining and Metallurgical Society of America, the Scranton Engineers Club, the Wyoming Historical and Geological Society, and the Franklin Institute of Philadelphia. His funeral took place Jan. 22.

Keeney Sends Invitations to Non-Union Operators

Reports indicate that the hold of the United Mine Workers on northern West Virginia is in great danger of being loosened if further attempts to launch an offensive for the purpose of putting fear in the hearts of miners and operators, particularly in the Fairmont field, are no more successful than those recently attempted. It is believed that John L. Lewis and his followers cannot intrench and that either they must clean house of non-unionism in that section or move out.

Recent investigation has shown that there are 577 tippable mines in the Fairmont field, only 180 of which are working at this time. Of the 180 working mines 57 are non-union, or 30 per cent of the field's production. Just prior to the strike of 1922 all the tonnage from northern West Virginia came from union mines. The field was 100-per cent union. Though many mines are idle the production from the field is healthy, being obtained from low-cost mines aided by non-union operations. The return for 1923 shows a larger production in the Fairmont field than in the banner year of 1918.

Frank Keeney, president of the Seventeenth district of the International, is said to be at his wits' end in this situation, which so vitally concerns him. Like those in Illinois, most of the mines in the northern West Virginia district—on the basis of number and not tonnage—cannot participate in coal trade with the present wage scale. Mr. Keeney is said to realize the predicament, but its relief is not in his hands.

He seems much worried. On Jan. 12 in Clarksburg he asked the owners of the non-union mines in the vicinity to meet him. There was no response. Again on Jan. 14 he made a similar request, but was no more successful. The non-union operators say: "Mr. Keeney can receive little benefit from us; he must deal with his men single-handed." And so he headed for Morgantown, it is said, where he intended to try the same stunt.

The general impression among operators is that he is sore pressed and that he is trying to create the impression of one seeking to relieve a troublesome situation. There may be a possibility of sectional agreements in April if other union officials take the same stand as Frank Keeney, provided, of course, he is sincere. It looks as if he really desires what he appears to be seeking.

Senator Borah Introduces Pinchot Bill To Regulate Coal Industry

Legislators Manifest Deep Interest in Measure—Closely Follows Decision in Kansas Industrial Court Case—Enactment Considered Unlikely—Much Discussion Certain

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Senator Borah, of Idaho, on Jan. 24, introduced in the Senate the coal bill drafted at the instance of Governor Pinchot, of Pennsylvania. While Senator Borah told the Senate, on introducing the bill, that he had not had an opportunity to study its details, he did declare that he is in thorough sympathy with the object and purpose to be attained by proper legislation along the lines indicated by this measure. "The coal situation," said the Idaho Senator, "is a very serious one, and, in my judgment, one with which Congress ought to deal. The bill ought to go to the committee so that those who are in favor of it may be given an opportunity to urge it. After full examination, I may find myself in perfect accord with the entire measure."

The bill is of unusual interest to legislators in that it is recognized as being the most competently and carefully prepared measure which has come before Congress. Numerous proposals to regulate the coal industry have been introduced and some have been considered at great length, but without exception these measures have been more or less crudely drawn. There is every evidence that this is the product of capable talent.

It is apparent that the drafters of the bill gave much attention to the decision of the Supreme Court of the United States in the Kansas Industrial Court case. In that opinion, it will be remembered, the high tribunal recited that since the adoption of the Constitution it never has been considered that the price of coal could be regulated by the government. On the strength of that statement, some have deduced that the court holds it to be unconstitutional to regulate the price of coal. The more general thought in that connection, however, is that the court simply made a historical statement, because it goes on to say elsewhere in the decision that the justification for classifying a business as being charged with public interest and subjecting it to regulation is "the indispensable nature of the service and the exorbitant and arbitrary control to which the public may be subjected without regulation."

In other words, the court made it perfectly plain that the power to regulate turns on a question of fact, which is whether or not the public would be subjected to exorbitant and arbitrary control if there were no arbitrary regulation.

The Pinchot bill uses almost the exact language of that decision. It does not give the proposed coal division

of the Interstate Commerce Commission power to fix prices and margins except "where in the absence of such regulation there exist exorbitant and arbitrary charges or there is danger thereof to the public." The coal division can issue an order of that sort only after having conducted hearings and having studied the particular situation so as to establish certain facts. Even in cases where the commission may decide that power resembling monopoly is being exercised, its order is subject to review by the courts, and holds only if the court sustains the finding of fact. This is a formula quite different from that applied by the Lever law. It is regarded quite generally as being an ingenious formula. The regulation of prices under such a plan might not be effective but the first impression in Washington is that the plan is constitutional.

Another lesson of the Kansas Industrial Court case is that there is no hard and fast line between a business subject to regulation and one not subject to regulation. A popular conception is that businesses fall in two distinct classes. They are either absolutely independent or fall into the public-utility class where they are subjected to sweeping regulation. The Kansas case makes it plain that each instance of regulation must be justified separately. That decision, in the opinion of some members of Congress at least, is that no business, and least of all the coal business, is free from regulation. On the other hand, the decision shows that few, if any, businesses can be subjected to general governmental control. As a result of this decision of the Supreme Court, members of Congress are generally of the opinion that the question is not so much whether the business or commodity is charged with the public interest but whether the specific form of regulation proposed is justified by specific facts and conditions.

It is regarded that the application of the rule-of-reason policy in the Kansas Industrial Court case carries with it an indication of what the Supreme Court might do in a compulsory fact-finding case. If it were established to the satisfaction of the court that the coal business is an indispensable service and if it were made to appear to the satisfaction of the court that the public had suffered through exorbitant and unreasonable prices, through shortage or the element of monopoly, the opinion among the lawmakers seems to be that the court would approve of regulatory legisla-

Clever Red Water

An ingenious use of a chemical last week enabled engineers to discover the source of water flowing persistently into the Radium mine of the Aluminum Ore Co. of America at Belleville, Ill. Three men were drowned when the flood originally broke into the mine from adjoining abandoned workings. When pumps could not dewater the mine, a search began to find out the reason why. A nearby creek running over the property was under suspicion. A little phenolphthalein, a chemical containing highly concentrated red color, was put into the stream a short distance upstream. Soon the water flowing into the mine was intensely red. The stream had been caught in the act. Its course is to be changed.

tion. Though the court might hold that the fixing of prices might not be justified, under the rule-of-reason policy, it well might hold that publicity of accounts properly could be required by Congress.

The consensus of opinion on Capitol Hill seems to be that the Pinchot bill will not pass, but it is certain to give rise to much discussion. It has been referred to the Committee on Interstate Commerce, in which Senator La Follette is in a position to obtain hearings or other consideration of this measure. If any disposition to deny that should develop, he probably would be as well satisfied to carry the matter onto the floor of the Senate.

36 Die in Mine Explosion At Shanktown, Pa.

An explosion at 3:51 p.m., Saturday, Jan. 26, in Lancashire Mine No. 18, of the Barnes Tucker Coal Co., at Shanktown, Indiana County, Pa., entombed 48 miners, 36 of whom were dead when taken out. The explosion occurred near the main heading. The last body was recovered at 2:30 p.m., Jan. 28.

The slope is 950 ft. long and on an 8-per cent grade, requiring rope haulage. The mine, which is in the Miller seam, is gaseous, requiring shotfirers and safety lamps. On the day of the explosion 51 men worked. Four men left the mine a few minutes before the explosion. Eleven men in section 6, right where open lights are permitted, made their escape through an opening far distant from the seat of the explosion. One man refused to accompany these eleven, wanting to reach the slope, and was the only man killed by the attempt. The cause of the explosion is not known, but is thought to have been gas and coal dust. Inspectors will hold investigation after ventilation is restored and the mine drained of accumulating water.

Practical Pointers For Electrical And Mechanical Men

Fatal Accident Is Narrowly Averted On Motor-Generator Set Lacking Ground

I was greatly interested in the story told by Mr. Emerson, of Alabama, concerning a ground on a rotary which might have killed someone. I remember a similar circumstance which occurred at one of our mines. A motor-generator set was installed in a new tile building; the floor was of concrete and the building was set on an old fill. For about two years this motor-generator set had operated without any trouble and incidentally without a ground connection.

One day something happened to the machine which the men in the mine did not understand. Some time during the day the oil-switch, through which the power passes to the motor, tripped open and shut down the motor-generator set. This is something that occurred occasionally under very heavy overloads, so the station attendant went into the substation and proceeded to restart the set, but each time he operated the starting handle of the oil switch a fuse on the line outside blew or the main circuit breaker opened up.

NEW MAN SHUNNED A.-C. WORK

The electrician at this mine was a new man and like many other electricians always shunned any work on alternating-current machinery. However, he was called in and after several attempts to start the machine without succeeding, the mine foreman, being quite anxious about the output of the mine for that day and the cost for keeping his men idle waiting for power, 'phoned the electrical department of the company for assistance.

Fortunately the engineer in this de-

partment, to whom the superintendent had explained his trouble, was a thorough and practical man, having had considerable practical experience with

electrical equipment at the mines previous to his technical training. Sensing the situation or realizing the possible danger to the inexperienced men at the mine, he instructed the mine foreman not to make any further attempts to start the machine or start any investigation or repairs until he arrived.

It was some time before this engineer arrived on the job because the mine was about twenty miles from the main office. When he arrived everyone particularly interested in the supervision of the electrical equipment at the mine was greatly puzzled as to the cause of the trouble.

FLASH AT BRUSH RIGGING

It had so happened that while the electrician was trying to start the motor-generator set a flash occurred at the brush rigging on the d.-c. generator and just as soon as the engineer arrived this fact was called to his attention. Everyone naturally expected that the trouble was with the direct-current end of the motor-generator set because this was the only place where there was any visual indication of trouble. Naturally enough the engineer made a careful investigation of the damage done on the direct-current generator and, of course, he examined this most logical point of trouble.

Much to the surprise of all who stood around watching for the trouble to be located the engineer directed two men to repair the damage on the direct-current generator and called upon the electrician to disconnect the motor leads from the wires leading to the oil switch. This was a surprising thing because no one expected or thought there was any trouble with the motor, as there was no evidence of any trouble there and, everything considered, there is not a great deal about a squirrel-cage induction motor that can go wrong.

Test of the stator winding of the motor showed a heavy ground. Without very much trouble the grounded coil was cut out and by the time this was done the men working on the d.-c. end of the machine were through and the motor-generator set was quickly put back into service.

The negative lead of the d.-c. generator on this motor-generator set ran directly outside of the substation to a heavy ground connection in a nearby

creek and also tapped to the rail for the return circuit from the mine. The machine never had been provided with a ground wire and when the coil in the motor winding became grounded, there being no way for the current to leak from the frame of the machine through the concrete foundation, it passed along the base of the motor-generator set and into the frame of the generator. There it jumped across one of the brush studs to the negative or ground connection on the generator.

It has always been a wonder to me that some one was not killed in this substation. Who knows how long the

FIG. 2—HOW THE LEAK PASSED THROUGH THE BASE OF THE MOTOR-GENERATOR SET

The circuit from the grounded coil in the motor passed through the base of the machine to the generator, thus charging the whole machine with a high voltage.

2,200-v. motor winding was grounded to the frame of the motor before the breakdown occurred on the d.-c. generator to the negative lead? There is a possibility that this condition existed for some time before the trouble was actually noticed. The machine could operate properly for some time under these conditions and probably did, and anyone touching the machine would have been in danger of being killed, especially if he had touched the frame of the machine with one hand and accidentally had his hand or foot on the steam heater near the motor-generator set. Needless to say a ground wire was attached to this machine before it was started again.

It was no fault of the engineering department that this machine did not have a ground, because time and again letters of instruction had been sent out to the colliery on this general subject, but with this case as an example the engineering department was able to make the argument for ground wires quite forcible and I am glad to say that many a man with our company has learned an important lesson from this case. It is not always that we learn such a good lesson without having some bitter experience and I am hoping that someone will get this lesson as we did, before a fatal accident occurs.

ELECTRICAL STUDENT.

FIG. 1—BROKEN-DOWN STUD INSULATION

By puncturing this insulation the high voltage of the motor passed to earth and formed the circuit to ground, which caused the starting switch to trip open.

Visual Aids to Car Management

BY DWIGHT GREEN
Pittsburgh, Pa.

After all is said the eye is the quickest organ to sense values. A simple chart will tell more than a page of type. This chart, with a tabulation affording exact data, gives a clear visualization of the car-standing capacity at the various tippie trackages of a group of mines. It notes the capacities of the loaded tracks separate from those of the empty and the length of track space for any given size of coal. It also designates mines having special trackage facilities, such as loading tracks for box cars.

By other charts the total car-standing capacity of any individual mine might be summarized and the capacity of an entire group recapitulated, though for this a different scale would have to be used. It will be found convenient to make the chart of such a size that it can be posted in the office and be readable from any point therein. By reducing its size photostatically it can be placed for use under a desk glass.

When the original chart is made of such proportion that it will reduce to pocket data-book size (say Lefax proportion), an interesting and valuable page is obtained for the general manager's dope book. Many similar charts may be prepared to show relevant information such as the number of cars

loaded at each mine and the tonnage per month and per year.

The profile at the bottom of the chart is intended to outline track grades at any one mine or the general conditions sought for at all the mines constituting the group.

Hints on Pipe Gaskets

The greatest difficulty I have encountered during my experience with gaskets has been to convince users that it is not necessary to tighten a thick, flexible metallic gasket with the same extreme pressure as must be applied to thin non-flexible gaskets.

The idea seems to prevail that a gasket, in order to prevent leakage, must have as little thickness as possible and must be squeezed so thin that the distance between the faces of the flanges is a very close approach to absolute zero. Very often when applying gaskets we see the engineer or pipe fitter slip a pipe over the wrench, thereby increasing the wrench's leverage and making it possible to increase still further the pressure against the gasket. As a result the gasket is squashed. If it is made of corrugated metallic material it is pressed out so flat that the corrugations can do no good whatever.

It is poor practice to slip a pipe over any wrench on any gasket because wrenches are generally made of a proper and safe length to fit the nuts for which they are intended, and nut sizes usually are standardized to fit certain bolt diameters. This is a logical safety measure that has been almost universally adopted so that the bolt will not be subjected to too great tension. An extra long handled wrench, unless used with extreme care, is likely either to break the bolt or strip the threads.

One serious objection to the very thin gasket is that no matter how it is constructed it can have but little expanding or contracting capacity; consequently all expansion and contraction must be taken care of in some other manner—by means of pipe bends or expansion joints. A thicker gasket, having elastic properties, will naturally take care of considerable expansion and contraction. In many cases I have known thick, flexible gaskets to take care of all of the expansion and contraction in the line under ordinary temperature conditions of non-super-heat practice.

Where temperatures are high or where temperatures fluctuate considerably, copper, brass and other metallic gaskets having a coefficient of expansion different from that of the joint should not be used. On account of the difference in the coefficient the gasket and the joint tend to expand and contract independently of each other. The tightly bolted joint, being much stronger than the thin gasket, will compel the gasket to expand and contract along with it. Breakage and leakage of a serious nature are, therefore, often the result. A gasket made up of steel which has the same coefficient of ex-

pansion as the joint overcomes this latter trouble entirely, but if it is thin and non-flexible it does not overcome or assist in overcoming the longitudinal expansion troubles.

Hence when applying thick, flexible metallic gaskets, be certain that a wrench of the correct length is used and then tighten only enough so that the leakage is prevented. Do not tighten too much. Any further tightening after leakage is stopped simply reduces the elasticity of the gasket and does not give it an opportunity to "breathe" as it should simultaneously with the expansion or contraction of the pipe line.

I therefore regard the matter of tightening as most important of all and want to impress it upon all users of flexible metallic gaskets. By being as careful in tightening the gasket as one is when tightening an ordinary steam-engine stuffing box, or when taking up the wear in a bearing, the best results will be obtained. Take it easy. Don't strain muscles, wrenches, bolts, gaskets, or anything. If directions are always carefully followed, much labor and fatigue will be avoided.

HENRY BOHMER, JR.

Use Your Head When You Use Your Hand

In a recent issue of *Coal Age* I read a story where a man touched with the back of his hand a machine that had an electrical leak on it. It is not my idea to encourage the practice of being careless in touching electrical equipment, especially when one knows that it is charged, but I think this is a point which may be stressed a little more than was mentioned in the article to which I refer.

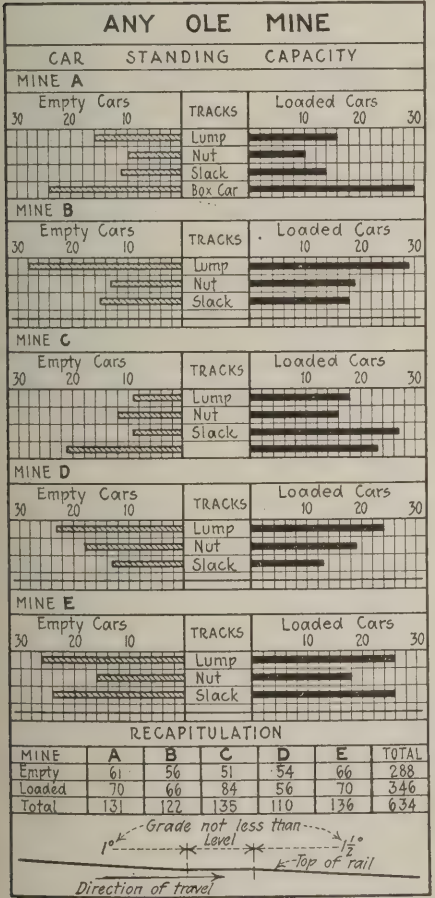

There is a strong tendency when the hand is placed upon an electrical conductor, or any piece of equipment which is charged with electricity, for the hand to automatically grasp the conductor and hold the person from breaking away. This is especially true with alternating current. Therefore, in testing for electricity if the back of the hand is used the fingers cannot close upon the conductor.

In this way it is very easy for one to be knocked away by the charge, or to pull his hand away quickly. This is no way to test a conductor for voltage, but where a person is going to work on a line and already knows that the switch has been thrown open it may be advisable to test the wires in this way to make doubly sure that it is safe to proceed with the work.

- 970.4 heat units.
- 104,320 kilogram meters.
- 1,023,000 joules.
- 754,525 ft.-lb.
- 0.066466 lb. carbon oxidized.

PUTS TRACK CAPACITY BEFORE EYE
A chart for office wall or desk which will convey at a glimpse what capacity for cars loaded or empty can be found at any of the mines of the company.

Problems In Underground Management

Loading Room Coal by Trips

BY G. E. ALLOWAY
Lexington, Ky.

A system of gathering coal from rooms in thin seams of coal not exactly new but still not at all in general use is being received with much popular favor in the mines of eastern Kentucky. It would have been almost impossible of operation with mules or large locomotives, but it fits in nicely with the low gathering locomotives now available.

Under the old method when rooms were driven 35 to 45 ft. wide a roadway was laid on each side of the room and only one car at a time could be loaded on either of these roadways. When the gathering locomotive came round to collect cars it got two cars from one room, but it had to make two trips up to the face and back in order to get them, and the miner waited a long time for the locomotive to come.

Now a curve is laid around the room face and this allows three to five cars to be placed alongside the face handy to the miner, the number of cars depending on the length of the face. The gathering locomotive can hitch onto a trip like this and haul it into the place or when loaded can haul it out just as well as it could a single car. The advantages are obvious.

The output per miner also is increased 25 to 50 per cent, for the time he loses is reduced to a minimum, and the miner does not have to shovel any of the coal two or three times to get it to the car, as was the case when the place was 45 ft. wide and the old method of laying the tracks was in use.

This method does not involve any unusual expense in laying track. All that is necessary when steel ties are used is to remove two spikes at the end of the permanent track and bar the entire curve and track forward to the face, replacing the same two spikes.

This method of tracklaying can be applied to almost any seam, for it requires no more room than the old method, and timbers can be set as close to the face as has been the custom with the usual trackwork. The locomotives are built as low as 25 in., and this allows them to enter any coal seam that can be worked profitably.

It will be said that it is useless to make such a provision where the men push the cars to and from the room face and the gathering cost is nil.

That might be true enough with rooms of favorable and easy grades where the miner is willing to push the cars, but there are almost sure to be excessively steep or dipping gradients, where the cars cannot be pushed by hand, and then a low locomotive with a track which curves around near the face will make the miner 25 to 50 per cent more productive and not make the gathering cost much greater than with hand-pushing methods.

Is a Board a Good Stretcher?*

BY GEORGE EDWARDS
Pikeville, Ky.

Many times it has occurred to me that some better means could be provided to carry an injured man. Stretchers of many designs are being sold, but most of them, unfortunately, are limber and cause so much movement to the patient when being carried that often he is so badly hurt in transportation that he never gets over his injuries. This is especially true when the injury is to the back, pelvis or thigh.

Just recently I saw an injured workman who, the doctor said, was in bad condition. The physician said much of the injury probably came from the long distance he had been carried without first placing splints to the thigh and knee.

I have been told that some coal companies have a board 7 ft. long and 20 in. wide (with three handholds on each side), the intention being that it should be slipped under an injured person regardless of his injury. He is lifted onto the board and onto the stretcher if there is one nearby. If not, he is carried on the board to the first-aid room in the hospital.

BACKWARD STEP FEARED

I have talked about this to several persons, and they feared that it would be a step backward and would encourage indifferent first aid, which, to my mind, is not true; for I believe a man who is capable would not hesitate to give the patient the best attention he could, and on the other hand should the unfortunate workman fall into untrained hands, which is often the case, if these boards which form a splint as it were, for the entire body were provided there would be fewer hopeless cripples. An objection has been raised

*This is an expression of opinion with which many readers will not agree.—EDITOR.

to the possibility that workmen would cut the boards into cap pieces and wedges. This could be overcome largely by painting a red cross on them and a sign calling attention to the object for which they were intended.

Dry Battery Always a Menace In Mine Blasting

BY W. T. GERMAN
Technical Representative, E. I. duPont de Nemours & Co., Inc.

A highly dangerous practice all too common in the mines consists in the use of dry-cell batteries for firing electric detonators. The contact points of a dry cell always are alive, and therefore the instant that the wires of an electric circuit touch these points a current flashes through the wires and explodes any electric detonator that may be connected in the circuit.

Recently a miner who was using a dry-cell battery fired a first shot and then returned to the face to connect the second without removing his leading wires from the contact clamps of the dry cell. The moment he joined the electric blasting-cap wires to the cable the shot fired, killing him on the spot. It was against the rules of the mine in which he was working to use a dry-cell battery, yet the miner who was killed had been employed there for twelve years and was considered a very careful man. This incident shows how necessary it is for mine officials to keep an unceasing lookout as to the kind of electric firing devices actually being used in their mines if they wish to prevent disasters.

New Powdered Coal Burner Is Tried Out

Experiments are being carried on by Washington University, St. Louis, in the use of pulverized coal at the Barnes Hospital, St. Louis, Mo., under new patents. A "carburetor" somewhat on the order of the one on gasoline motors, where the proper mixture of air and coal is fixed, is one of the features. The results for the first ten days were overwhelmingly in favor of this coal against the hand- and stoker-fired systems. There was no smoke, which in St. Louis is a big feature, and four scoops of ashes was the result of the 10-day trial. The carburetor delivers forty parts of air to one part of coal under the system devised by Wm. H. Whittaker, of Shelbyville, Ill.

Discussion

Principles Which Underlie the Satisfactory Humidification of Mine Air

Not Necessary to Use Baffles or Radiators—Current Split to Prevent Loss of Heat and Moisture Before Reaching Live Workings

THAT the temperature of mines is only a few degrees warmer in summer than in winter is well known, while the change in the outside temperature varies greatly in these two seasons of the year. It also is well known that the capacity of air for absorbing and retaining moisture increases with its temperature.

Bearing these facts in mind, it is easy to see that summer air is capable of holding a far greater weight of moisture per unit volume than winter air. Air is said to be saturated when it contains all the moisture it can hold at its present temperature. Therefore, it is clear that a comparatively small quantity of water vapor will fully saturate a greater volume of air in winter than in summer.*

Many confuse the idea of saturation with the weight of moisture carried in a given volume of air, whereas the two expressions have no relation to each other. For example, the same weight of water vapor that will fully saturate a given volume of air at 30 deg. F. would give but 10 per cent of relative humidity in the same volume of air at a temperature of 100 deg. F.

The safe operation of a dry and dusty mine requires not only the systematic removal of the dust, as far as that is practicable, but the mine air must be humidified. For that purpose the simplest and most practical means employed is the introduction of exhaust steam into the intake air current.

As we all know, the steam entering the intake airway of a mine produces a fog that fills the passageway for a considerable distance beyond the point where it enters. As the heat of the steam passes into the air the fog gradually disappears. The water vapor forming the steam is absorbed by the air and the temperature of the latter is considerably increased.

The warm air current now laden with moisture carries this into the mine and, as its temperature falls to the lower temperature of the mine workings, much of the moisture is deposited there and serves to keep the dust in a more moist condition and renders it less dangerous.

One difficulty experienced in humidifying mine air is the tendency or desire to circulate the required volume of air under as low a water gage as possible, in order to reduce to a minimum the power required for ventilation. This naturally means a smaller quantity of steam exhausted from the engine driving the fan and a comparatively larger volume of air to be humidified. The result is that this large volume of intake air is not saturated and produces a drying action in its passage through the mine. This has led many to discount and abandon the idea of humidification by the use of steam.

Others have been led into the error of using live steam in addition to what exhaust steam was available. In one instance I found a 2-in. pipe installed to deliver live steam at 160-lb. pressure in a mine where there was insufficient exhaust steam. In another instance where the results had been unsatisfactory, the mine superintendent concluded that the trouble was because the steam and air did not mix thoroughly.

To overcome this supposed difficulty he had installed a system of baffles, deflectors and check plates in the intake air course. This so obstructed the flow of air into the mine and increased the water gage and power required for ventilation that it became necessary to bring into use a spare boiler in the power house and employ an extra fireman on the day shift. The power required to drive the fan was increased from 70 to 235 hp., and the volume of exhaust steam was 3.3 times what it had been previously.

Let me say here that the use of baffles to insure the mixing of the steam and air is wholly unnecessary. The expanding steam mixes rapidly with the air within a short distance after entering the current. It is a good plan to place the steam jet or orifice at the center of the entry, so that it will blow in the direction the air is moving.

Another costly operation frequently resorted to is the use of radiators to heat the air. To my mind, the use of a radiator for that purpose is inefficient, and the device is cumbersome and costly to install. Nothing is more efficient than the direct contact of the steam with the air.

In humidifying a mine, my practice has been to use all the exhaust steam available from the engine driving the fan and from other engines at the plant, as far as that is practicable. It always is advisable to ascertain if the volume of air entering a mine is

greater than what is required for its efficient ventilation, after repairing the stoppings and making any changes necessary to reduce the required circulation to a minimum. This is an important factor if the best results are to be obtained. To avoid the loss of heat and moisture before the air current reaches the live workings it should be conducted by the shortest practicable route.

In one instance that I observed in a West Virginia mine the intake air was well heated and humidified at the entrance, but the moisture was practically lost before reaching the live workings, because of the excessive distance the air had to travel. This was finally overcome by the erection of one or two air bridges and splitting the circulation. My experience is that steam humidification along the lines I have suggested is not only the surest way of solving the dust problem but does this in the simplest and cheapest manner possible. Applied intelligently, it will do more to lay the dust than any quantity of sprinkling.

F. C. CORNET,
Mining Engineer.

Quaregnon, Belgium.

Veteran Among Coal Producers

Your readers may be interested to hear of what in my belief is the oldest of producing mines on the American continent, Caledonia No. 4, an operation now being conducted by the British Empire Steel Corporation. This mine was opened in 1865 and is still in operation. It has produced 2,400 tons in a single shift and 3,300 in a double shift. It is still capable of a maximum output of 1,500 tons and has a daily average production of 1,200 tons. The coal is transported by an endless rope haulage over 28,000 ft. long. The depth of the shaft is 180 ft. This has been equipped since 1894 with self-dumping cages. I would like to hear of any mine having a longer life and a more extended rope or a longer haulage, especially one with such a well-sustained output.

ALEX McDONALD.

Glance Bay, C. B.

Cement Output and Shipments High for December

Production of portland cement during December, 1923, according to a report by the U. S. Geological Survey, based partly on estimates, totaled 9,997,000 barrels, compared with 12,603,000 barrels in the preceding month and 8,671,000 barrels in December, 1922. Shipments for the month were 6,408,000 barrels, compared with 10,251,000 barrels in the preceding month of November and 4,858,000 barrels during December, 1922. Stocks at the end of December amounted to 10,581,000 barrels, compared with 6,991,000 barrels at the end of the preceding month (according to revised figures) and 9,108,000 barrels at the end of December, 1922.

*How true this is may be seen by the rapidity with which the surface of the ground dries in summer as compared with the slowness with which it is dried in winter. In cold weather, however, the mine raises the temperature of its air and so reduces its saturation, whereas in summer it decreases the temperature and so completes the saturation.—EDITOR.

Production And the Market

More Inquiries for Soft Coal; Little Gain In Actual Business; Miners' Action Awaited

Inquiries from consumers of soft coal are growing, but actual business has not increased much, caution appearing to be the guiding influence of buyers, many of whom are awaiting the outcome of the miners' convention at Indianapolis. In the West the demand for domestic coal is much heavier because of the cold weather, and increased production is causing a growing volume of slack. Production continues heavy with considerable coal going on contracts or to stockpiles, while reports from some industrial centers show that current consumption is slightly heavier. The strike of the Nova Scotia miners increased the inquiries from Canada and some actual business is reported. Contracting continues to lag in most markets and while some contracts are reported as having been closed, the tonnage involved has not been large. Some operators are favorably situated as to orders between now and April 1.

Little Change in Conditions Observable

Conditions generally are little different from the early part of the month. Only in scattered sections have any of the mines reopened that were closed last autumn because of "no market" while operators in some parts of central Pennsylvania complain of the lack of labor in those mines that are working.

Coal Age Index registers 187 as of Jan. 28, an increase of five points when compared with the previous week, with an average price of \$2.26, an advance of 1c.

The Middle West markets are kept fairly active by good demand for domestic coals, although prices have not advanced. Some of the mines which were closed have been obliged to reopen and the entire outlook is much brighter. Domestic tonnage in both the Mount Olive and Standard districts is moving strong, but car shortage in both fields has interfered to some extent with coal movement. Dealers in St. Louis report movement to be 100 per cent, but the demand is for the

cheaper coals. Business in Kentucky is good, colder weather having created an active demand for prepared coals accompanied by a good car supply. There is better buying by utilities and heavier consumption of gas has resulted in a better demand for gas or byproduct coals. Stocks in yards in the Northwest are being rapidly depleted, forcing the owners into the market for replenishments.

A general improvement is noted throughout Ohio. There was a slowing down of car supply accompanied by slower movement of coal. Heavier demand for smokeless coals from Chicago buyers has tightened the various markets and there is a heavier call for domestic sizes. Reports are that many non-union fields are gradually getting back to the 1917 wage scale. Both steam and contracting situations are quiet. There is a trifle better outlook in the spot market at Pittsburgh.

Restriction of production caused a slight stiffening of quotations for Southern coals in New England, but there are no favorable developments in the textiles and almost no signs of buying in any direction. Along the Atlantic seaboard everything is quiet.

The market for domestic anthracite is slow and some independent coals were quoted at figures close to company quotations.

Production of soft coal slackened during the week ended Jan. 19, according to the Geological Survey report, dropping to 11,621,000 net tons, a decrease of 328,000 tons when compared with the preceding week, while the output of hard coal during the same period increased 44,000 net tons when compared with 1,840,000 tons, the output of the week ended Jan. 12.

Midwest Works Hard

Reopening of a great many of the mines that had shut down during the autumn raised the early January output of the Midwestern fields tremendously, especially during the past week. Some mines have been running every day and

more are going to work. The zero weather that prevailed through most of the week kept the domestic market at fairly high pitch. The flow of most coals was steadily so strong and cars so numerous that prices did not ascend. In fact they had the inevitable tendency to sink on screenings. Southern Illinois screenings sold down to \$1.75 and this 15c. drop was equalled in other competing fields. A great deal of Eastern smokeless coal has been flowing into the Midwest region. The demand is strong, with the result that Pocahontas lump sells in Chicago readily in spite of the slowly ascending price.

Mt. Olive field conditions have been materially improved recently. A good domestic tonnage is moving, and though steam is hard to find, the tonnage keeps moving with the assistance of railroad help for nut and egg sizes. Four and five days is the rule in this district. There has been a car shortage here that has stopped production to some extent.

In the Standard field lack of steam business has interfered with working time at several mines and car shortage has to some extent slowed up production. The demand has been good for 6-in. lump. Steam is more difficult to move

than any other size but the price of steam continues to show cost. Working time averages close to 5 days a week.

All St. Louis dealers report their equipment moving 100 per cent, but demand for coal is mostly for cheaper grades. A little high grade is moving and there is a good demand for coke. Anthracite and smokeless are slow. There has been no reduction in retail prices. The dealers' supplies are pretty well gone, excepting on high-grade fuels. Wagonload steam continues fairly good. Local carload steam is slow. Country steam is fairly good and country domestic is active on the cheaper grades.

Kentucky Business Is Good

Cold weather all the way to the gulf has resulted in a more active demand for Kentucky prepared sizes, and some of the mines that had been working about two days a week are getting in four days or better now and are finding business fairly good. Car supply is adequate and though prices are showing no real improvement, the situation is more promising. Steam demand is somewhat better than it has been and utilities are buying more freely.

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

Index	1924			1923
	Jan. 28	Jan. 21	Jan. 14	Jan. 29
Weighted average price	187	182	182	342
	\$2.26	\$2.25	\$2.20	\$4.14

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Eastern Kentucky prime block coal has been a shade firmer, with the market running to a maximum of around \$3.50 on better grades. Egg and nut sizes, along with lump sizes, show no change, but screenings are somewhat weaker. Utility buying is better and gas companies, meeting with a heavy demand for gas, have been placing better orders for gas or byproduct coal. Car supply is holding up well.

Northwest Trade Brisk

A succession of cold waves throughout the Northwest has created an active demand for coal in both city and country. Stocks are moving out of the yards at a rapid rate, but there is plenty of everything in the way of coal and coke. Several cargoes at Milwaukee remain to be unloaded. Jobbers who depend on rail supplies complain that receipts are slow owing to weather influences and strikes at some Eastern soft coal mines. There have been no changes in prices.

A big run on coal has developed at Duluth within the past week and all Head-of-the-Lakes docks are working to capacity. The result of the run has been to strengthen the tenor of the market without actually increasing prices. In fact the losses recorded last week have not been recouped, and bituminous is at the same level as quoted last. The

anthracite market at Duluth is struggling to hold its own as best it can. Pea is reported as fast disappearing.

West Continues Busy

Mines through the Southwest continue to operate full time as winter holds on. However, none of those closed for the summer and not reopened at the beginning of the season has resumed operation as a result of improved business, and there has been no difficulty in obtaining sufficient cars to move the coal as rapidly as it has been mined. Retailers have been compelled to make delayed deliveries on some grades of domestic coal, but there always has been sufficient coal of other grades to tide over.

The slack market in Utah is stronger for office buildings and the like are buying again. Weather continues very cold. The greatest trouble now is the moving of intermediate sizes. If the situation does not improve it is expected that some mines will be closed temporarily. Some of the biggest operators are getting behind on their lump orders as a result of this condition. Working time is around four days a week.

The coal market in Colorado is still showing signs of life and mines worked an average of five days last week. Demand for all sizes is coming in steadily and very few unconsigned loads at the mines were reported. "No Market" is slowly declining with less than 20 per cent of the total working time lost last week attributed to this cause. Prices are unchanged. The transportation equipment and car supply have been very favorable throughout the state except in Routt County, where weather conditions have prevented considerable movement of commodities.

Domestic Demand Strong in Ohio

General betterment of prices and a slowing down of both car supply and the movement of coal were the features of the Cincinnati coal market last week. The advance in prices for smokeless coals was attributed chiefly to the demand of Chicago buyers for "car numbers." Cold weather and the demand for domestic coals caused an upturn. There is little or no talk of contracts and some buyers are waiting for the outcome of the miners' convention before committing themselves. Retail business is on the same basis as earlier in the month. Exceptional coals are being quoted at \$3.75@\$4 for block, and \$2.75@\$3.25 for egg.

At Columbus lower temperatures have stimulated the domestic trade to a small degree, but the general market is draggy. Although retail stocks are comparatively light, dealers are slow to order, and buying on the part of householders is on a hand-to-mouth basis. Steam coal demand is quiet, due to large reserves, and the utilities and railroads are making small additions to their present supplies. Mines in the Hocking Valley and other field are gradually resuming operation. Contracting is quiet, both operators and buyers watching the outcome of the Indianapolis convention. Reports to the Southern Ohio Coal Exchange show that for the week ended Jan. 12 the total output of 446 mines reporting was 196,178 tons out of a full-time capacity of 682,824 tons. Of the shortage "no market" was responsible for a loss of 453,115 tons.

There is an active demand by domestic consumers for Pocahontas and other smokeless fuels at Cleveland. Eastern Ohio operators also report a heavy demand for their coals. Retail dealers are busy replenishing their stocks and industrial plants are adding to their stocks of steam coals, not willing to take any chances. Buyers as a rule are watching the market for bargains and are keeping distress coal down to a minimum. Some of the mines in eastern Ohio which were closed during the past couple of months have reopened.

The spot market at Pittsburgh was just a trifle dull last week, but is not as poor as in the first week of the year. Production is somewhat heavier. The change is only slight, however, rail mines running a trifle over 50 per cent as compared with about 45 per cent before the holiday season. Only a small part of the increase is attributable to the demand for domestic coal. The Pittsburgh district continues to feel sharp competition from the nearby non-union fields.

The soft-coal market at Buffalo shows comparatively no change, the chief demand being for slack. Severe cold weather resulted in increased inquiry, but prices were not affected.

New England Sees Few Signs of Buying

In New England there are again some signs of firmer prices on Pocahontas and New River. The advance that materialized last week, however, was due far more to restricted production than to any appreciable improvement in demand. The light tonnage available at the Hampton Roads terminals made possible a gradual lift in quotations the first of the week from \$4.75 to \$4.90, and near the close of the week from \$4.90 to \$5.15. No actual sales at the latter figure were reported, but the fact that a few agencies are naming \$5.25 shows a purpose to try out the market on the basis of current mining. All these prices are per gross ton f.o.b. vessel at the loading port, but there has begun to be a corresponding movement on coal in storage for delivery inland. Prices on cars Boston and Providence have in some cases been advanced to \$6.15@ \$6.25, also per gross ton.

In the textiles, in shoes and in the paper trade there are no favorable developments. Reserves of coal in many cases are nearly at the maximum and there are few signs of buying in any direction. There is a certain response to strike talk, but it is by no means characteristic, and there seemed to be little chance that consumers will enter the market in any number during February.

All-rail there has as yet been no changes. It would take a material advance in the price of smokeless coals from West Virginia via the water route to approach the present delivered cost of coals from central Pennsylvania even at the minimum Clearfield rate. That one or two distributors of these coals are beginning to move their offices from Boston to Springfield, Mass., in order to be in closer touch with the actual buyers of those coals shows that the area nearer tidewater is being conceded to the shippers of Pocahontas and New River.

More Inquiries Along the Seaboard

Indications point to better buying and more inquiries for soft coal in the New York and Philadelphia markets. Some New York houses have been asked as to shipments to Canada and there has been an increased demand from the Dominion due to the strike of miners in Nova Scotia, both all-rail and water deliveries. Large consumers have shown a tendency to take in more coal, but they are not increasing their orders to a large extent. Most consumers are watching developments at Indianapolis. Contracts continue to be in the making and although \$3.25 is generally accepted as the contract figure for the better coals, some operators, it is said, are willing to take less. The market at Baltimore is flat, with prices remaining without change.

West Virginia reports a better demand for its coals in the West than in the East, but production has not been stimulated to any extent. Output in Virginia is about 60 per cent of capacity. Weather conditions have caused an improvement in the wholesale domestic demand at Birmingham. Dealers have been enjoying a better run of orders and are calling on the mines for replenishing stocks. Not much improvement is noted in the demand for steam coals.

The export market is a trifle more active, due to inquiries from Europe and from Canada, but the amount of new business placed is said to have been small. There was a sudden spurt in the movement from Baltimore, one vessel taking more than 10,000 tons to Genoa, Italy. During the first twenty days of January dumpings of cargo coal amounted to 38,458 tons, as compared with 3,390 tons during the corresponding period of last year.

No General Improvement in Anthracite Demand

Despite the more seasonable weather the anthracite trade fails to show any general improvement. Retail dealers are fairly busy, but production is sufficiently heavy to meet their demands. Yard bins are well filled and consumers of the domestic sizes are beginning to hold off in renewing their supplies. Stove and chestnut sizes continue to be the heaviest in demand, but there is no shortage. Straight lots of these coals of independent origin are held at slightly advanced quotations than when taken in conjunction with either egg or pea coals, which are draggy in most markets. Welsh anthracite is being offered to the trade in Baltimore as well as in New York, but comparatively few orders are reported as having been placed.

Utility Coal Consumption Gains Rapidly

Central-station plants were heavy consumers of coal in 1923. The reports of the Geological Survey show that whereas in 1919 these utilities used 96,200 net tons of coal daily for the generation of power, the daily consumption rose to 101,400 tons in 1920, but fell to 93,700 tons in 1922. In seven of the first eleven months of 1923 the quantity of coal consumed averaged about 110,000 tons per day and the average for the year was over 100,000 tons. Oil used by central stations also gained in 1923, the average daily consumption ranging from 32,600 barrels to 45,000 barrels. The average in 1922 was 36,200 barrels per day.

Foreign Market And Export News

British Production Registers Another Increase; Export Demand Slow

Production of coal in Great Britain was 5,747,000 tons during the week ended Jan. 12, according to a cable to *Coal Age*. This was an increase of 1,272,000 tons over the previous week's output and compares with 5,607,000 tons during the corresponding week of last year.

The South Wales coal market is reported to be quiet, due probably to the railroad labor trouble, while many of the mines have either stopped operations or are working on a curtailed schedule.

Many mines are well supplied with orders for immediate shipment, but others have filled their recent contracts in record time and are now running short of business. Foreign customers are holding their business for the fall in prices which they anticipate will accompany the decline in business.

The European demand is slower. Italian business being especially deficient. South American business is also very slow. Though the current export demand is fairly active the market is slack.

The Newcastle market is more stable though the recent strong position has been materially weakened by the arrival of a considerable amount of German coal in Belgium. Most of the mines are well booked ahead.

Hampton Roads Market Brisk

Business was more brisk at Hampton Roads in all branches last week, with prices stiffening, and inquiries on the increase. Car shortage on the N. & W. and C. & O. contributed to a marked increase in prices, due to the consequent lack of coal.

Foreign inquiries improved, while bunker demand was good and coastwise business fair. Improvement was noted for the first time in several weeks.

The tone of the market was strong, and the outlook for business good. Supplies of coal were low, but operations at the mines had been reported improved, and no shortage at tidewater was anticipated.

French Coal Market Active

The French coal market is normal following the holiday season and it is expected that production figures for January will be higher than for December. Demand for domestic coals is sufficient to absorb production and some improvement is noted in the call for house coals.

Owing to the difficulty in securing shipments, work was stopped for a few days the second week of the month in the Sarre district, reducing deliveries from that district to France. The Sarre collieries it has been announced are re-establishing their natural outlets with southern Germany.

Lack of rolling stock is keeping down the receipts of coal from Belgium. Imports of British industrial coals are larger, while house coals are purchased only when needed, because of the high prices.

Deliveries of indemnity fuels during December amounted to 190,200 tons of coal, 361,900 tons of coke and 31,900 tons of briquets.

During November France exported 206,277 tons of coal as compared with 121,915 tons in October. Coke produced during November was 182,974 tons, a decrease of 7,249 tons when compared with the previous month, while 431,592 tons were imported as compared with 282,806 tons in October.

Foreign Coal Trade Notes

Denmark imported 2,571,139 metric tons of coal during the first ten months of 1923, according to the report of Consul General Letcher, at Copenhagen, to the Department of Commerce at Washington. This compares with 2,263,260 tons imported during the corresponding period of the previous year.

The Polish coal production for the first nine months of 1923 is reported at 27,803,816 metric tons, or an increase of about 1,700,000 tons over the corresponding period of 1922.

Assistant Trade Commissioner Cremer, stationed at Rio de Janeiro, re-

ports to the Department of Commerce at Washington that the Minister of Transportation and Public Works of Brazil has directed the general manager of the Central of Brazil Railway to take steps to enter into direct negotiations with the mining companies in the United States and England regarding coal supplies for that railway.

Rate Adjustment Hearing

A hearing will be held on Feb. 7 at New York City by the Coal & Coke Committee, Trunk Line Territory, on a carrier's proposal to adjust rates on anthracite from mines on the D. & H., D., L. & W., and the N. Y., O. & W. Rys. to stations on the Grafton & Upton R.R. It is proposed to reduce the rates on prepared sizes of anthracite from points on the D. & H. and D., L. & W. from \$5.04 to \$4.91 and on pea and No. 1 buckwheat coals to West Upton, Upton and Hopedale, Mass., from \$4.91 to \$4.79 per ton. Adjustments are proposed from points on the N. Y., O. & W. Ry to make rates similar.

M. & W. Removes Differential

Largely through the efforts of the Monongahela Coal Association the freight rate differential on carload shipments of coal over the Morgantown & Wheeling R.R., now a part of the Monongahela Ry., between Randall and Cassville has been removed. Heretofore coal shipped over the subsidiary of the Monongahela has had to bear a freight charge of \$47 per car. In the future, under the new ruling, coal shipped over the Morgantown & Wheeling will be subjected only to the same rate as coal shipped from points on the main line of the Monongahela.

Defers Rate Inquiry

The Interstate Commerce Commission has indefinitely postponed its investigation into rates on anthracite and on bituminous coal from points in Pennsylvania and West Virginia to New England and northern New York destinations. Hearings were to have been resumed Jan. 28, but were canceled because statistics that were to have been submitted were not ready. It is understood the investigation will be resumed about the middle of February.

Coal-Road Earnings Up

The Norfolk & Western Ry. reports gross earnings of \$8,074,152 in December, 1923, against \$6,960,753 in December, 1922, and \$7,218,894 in 1921. Net operating income amounted to \$2,377,969 in 1923, against \$642,677 in 1922 and \$2,138,886 in 1921. Gross earnings for the whole of 1923 totaled \$95,494,687, against \$90,314,743 in 1922 and \$80,760,590 in 1921. Net operating income totaled \$19,877,677 in 1923, against \$18,624,468 in 1922 and \$14,870,021 in 1921.

The Delaware & Hudson showed net operating income of \$531,443 in December, 1923, against \$74,892 in the same month in 1922 and \$153,771 in 1921.

Net operating income for the full year 1923 totaled \$6,512,344, against \$1,216,689 in 1922 and \$7,076,803 in 1921.

The Delaware, Lackawanna & Western reported net operating income of \$1,091,959 in December, 1923, against \$329,130 in 1922 and a deficit of \$73,349 in 1921. For the year, this road reported net operating income of \$13,443,543, against \$6,669,022 in 1922 and \$12,997,084 in 1921.

N. Y. Central Loadings Heavy

Average daily coal loadings for the second week of January on the New York Central lines amounted to 2,505 cars, which was an increase of 33½ per cent over the daily average for the month of December, according to a statement issued by the company. The average for the second week of January was larger than the daily average for any month of 1923 with the exception of January, when the country had not yet caught up with the shortage due to the prolonged miners' strike. The daily average coal loadings for the first week of January was 2,161 cars.

Northwest Wants Rate Decision

The long delay of the Interstate Commerce Commission in giving a decision on the Illinois-Minnesota rate case, which was heard a year ago in July, is causing much adverse comment among coal men in the Northwest. It is pointed out that \$35,000,000 is invested in the docks at the head of the lakes and that these docks are supposed to supply the Northwest. Many feel that they are being unfairly discriminated against by the commission and that a continued delay will make the dock trade suffer.

As the situation stands Illinois coal can be brought to Twin Cities for \$3.46 a ton, a distance of 700 miles. Eastern coal comes to Buffalo from the mines for \$1.82 and from Duluth to Twin Cities for \$1.76, or \$3.58 for the total rail haulage of 250 miles. To this must be added the water freight of \$0.45 a ton, making a total of \$4.03. The docks contend that they cannot exist long against this competition.

Even Duluth itself is not immune from the Illinois coal bugaboo. It is being sold there under the name of "Illinois lump," and the dealer charges \$11.25 a ton, or two tons for \$22. Householders buy it under the impression that it is "part anthracite," and it looks much like it in the medium sizes. Added to other Illinois advantages is that cars can be reloaded with grain or other material for the return trip.

Arguments will be heard Feb. 19, in Minneapolis, on the request that has

been made by the docks for \$1.66 increase in the anthracite rate to Twin Cities, all rail. Minneapolis independent dealers are opposing this, as they can at present undersell the Duluth coal.

Association Activities

The eleventh annual meeting and banquet of the Cincinnati Coal Exchange was held at the Hotel Gibson, Cincinnati, on the evening of Jan. 24. About 150 members of the organization and friends were present. Vice-President Edward Harper, in the absence of R. S. Magee, who is in California, presided. Colonel Charles A. Moriarity acted as toastmaster. A. Julius Freiberg, president of the Cincinnati Chamber of Commerce, of which the coal exchange is the largest subsidiary, was present and felicitated the coal men upon the work that had been accomplished during the year. One striking utterance was the statement that the onslaught of public opinion against coal, railway and other business interests should be met four-square. "When an issue develops," said Mr. Freiberg, "there is only one way to meet it, and that is to stand and fight." Other speakers of the evening were W. S. Battle, Jr., claim agent for the Norfolk & Western Ry.; W. C. Hull, assistant to the traffic vice-president of the Chesapeake & Ohio Ry., and J. M. Dewberry, coal and coke agent for the Louisville & Nashville. Tribute was paid to Victor White, Kuper Hood, Charles A. Tribbey and Jacob Brady, who died during the year.

The Southern Ohio Coal Exchange held its annual meeting at Columbus, Jan. 25, when it was voted that the exchange be represented in the four-state meeting between operators and miners at Jacksonville, Fla., Feb. 11. Dr. T. R. Biddle and J. S. Jones were chosen as delegates and James H. Pritchard and O. S. Newton as alternates. The following officers were elected: T. R. Biddle, president; George H. Barker, treasurer; W. D. McKinney, secretary, and James H. Pritchard, commissioner of mining.

Obituary

Ryburn Pinckard, superintendent and general manager of the Norton Coal & Coke Co., of Nortonville, Ky., died at Nortonville, Jan. 18. Mr. Pinckard was superintendent of the byproduct plant of the Woodward Iron Co., Birmingham, Ala., for several years, going to Nortonville about three years ago. He was 41 years of age and spent a great part of his life in the Birmingham district, where he was well known in industrial circles. Burial took place Jan. 20.

George W. Leckie, chief engineer of the Leckie Coal interests in southern West Virginia and Kentucky, died at his home at Welch, W. Va., on Saturday, Jan. 19. Mr. Leckie was born Feb. 2, 1881 at Shendoah, Pa., and after being graduated from Girard College, at Philadelphia, he entered the employ of the Wentz interests, spending fifteen years with that company at the Mary D. and Lehigh Collieries. In 1917 he was made chief engineer of the Leckie Coal companies and moved to Welch. He is survived by his wife, and by four children. Funeral services were held at the Presbyterian Church at Welch on Tuesday, Jan. 22, burial being at Bluefield, W. Va.

Coming Meetings

Rocky Mountain Coal Mining Institute, Winter meeting, Feb. 13-15, Albany Hotel, Denver, Colo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

New England Coal Dealers' Association. Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

American Institute of Mining and Metallurgical Engineers. Annual meeting Feb. 18-21, 29 West 39th Street, New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

Northern West Virginia Coal Operators Association. Annual meeting Feb. 12, Fairmont, W. Va. Secretary, J. O. Caldwell, Fairmont, W. Va.

Upper Potomac Coal Association. Annual meeting March 3, Cumberland, Md. Secretary, J. F. Palmer, Cumberland, Md.

News Items From Field and Trade

ALABAMA

A spur track has been constructed to the mines of the **Hilliard Coal Co.**, about four miles from Jasper, Walker County, by the St. Louis & San Francisco R.R. The company has lately completed a large tippie at its mine.

The **Sunlight Mining Co.** has installed a large steam shovel and completed a large washery at its stripping operations in Walker County, near Jasper. Erection of a number of houses for employees also is contemplated at an early date.

COLORADO

The **Colorado State Land Board** has leased to the **Pacific Steel Co.**, of Los Angeles, Calif., 6,318 acres of state coal lands classified as Fort Lewis school lands, located in La Plata County, near the New Mexico-Colorado border. The **Pacific Steel Co.** made application to the board for the lease last September; the lease was approved by the Attorney General, but formal papers were not drawn and the lease signed until the early part of January. The company will pay to the state a royalty on all coal mined. State officials predict that this lease presages the exploitation of the hitherto undeveloped coal resources of La Plata County.

During the month of December **Colorado** mines produced **1,037,772 tons of coal**, this being 95,079 tons less than the production for the same month last year. The yearly production of 10,322,258 tons shows an increase of 318,648 tons as compared with the amount of coal produced during 1922. The average number of men employed in and around the mines was 13,232 and average number of days worked per mine was 160.9.

ILLINOIS

The U. S. Supreme Court has affirmed the decision of the Federal District Court at East St. Louis, in the case of **Walter G. Space vs. the Illinois Fuel Co. of Sparta, Space**, who resides in Minneapolis, brought suit for alleged breach of contract, alleging that the coal company contracted to ship him 12,000 tons of coal from the Sparta mine in 1920. The district court gave him a verdict for \$12,000, which was sustained by the Court of Appeals at Chicago. The judgment with interest now totals \$15,000.

January has been a good month for the miners in the immediate vicinity of Belleville. It has been a better month, in fact, than any in the last two years. All except eight mines in the subdistrict, where 10,500 men follow the occupation, are operating daily. The only mine in the vicinity which has not reopened is the Superior, owned by the Perry Coal Corporation.

Another petition in bankruptcy against the **Southern Gem Coal Corporation** was filed last week in East St. Louis. This time miners formerly in the employ of the company, and who have suffered by the fact that the company missed two payrolls, have filed an intervening petition claiming \$100,000. The first receivership, ordered upon petition of minority creditors, has been dissolved and another petition from the same source was expected.

With an output of 4,902 tons in four hours, the **Kathleen mine of the Union Colliery Co.** at Dowell established a new record on Jan. 12. The day's output required 101 railroad cars for transportation. The mine has a capacity of 8,000 tons daily.

INDIANA

Delegates representing the **Indiana Bituminous Coal Operators' Association** will attend the mine wage conference at Jacksonville, Fla., Feb. 11, unopposed, and with full power to act for the operators. It has been announced by Phil H. Penna, secretary of the association. Representing the operators will be M. L. Gould, president of the association; Alfred M. Ogle and E. D. Logsdon, of Indianapolis; Phil H. Penna, Will J. Freeman, John A. Templeton and Hugh Shirkie, of Terre Haute, and David Ingle, of Evansville.

Officials of District 11, United Mine Workers, have been notified that the **James Devenold mine**, near Burnett, employing about 150 men, has been closed down. The mine had been operating under the co-operative plan, under which the company was selling stock, valued at \$50 a share, to the employees. Pay day found the miners 25 per cent short in wages and the balance due was credited to them in the company's stock, it was reported. Later they learned the mine was not making expenses, which led to its closing.

The 1924 first-aid meet of **Indiana coal miners** is to be held June 28 in the fair ground at Princeton, according to Cairly Littlejohn, chief mine inspector of the State Department of Mines and Mining, who attended a joint meeting of miners and operators with representatives of the federal Bureau of Mines at Terre Haute recently to arrange for the meet. The election of officers of the Joseph A. Holmes Safety Association was held at this meeting and the following men were named: William Rohl, president of the local miners' union at Princeton, president; Alfred Taylor, secretary of the Princeton Chamber of Commerce, secretary; William H. Raney, superintendent of the General Fuel Corporation, Princeton, vice-president; W. W. Cox, superintendent of the Francisco Mining Co., treasurer. These men are to arrange for the state safety meet.

The **Shagley Coal Co.**, of Terre Haute, has filed preliminary certificate of dissolution.

KENTUCKY

Two or three coal-tax bills have been introduced in both the House and Senate of the **Kentucky General Assembly** since Jan. 19, providing for a tonnage tax on coal based on either 2½ or 3 per cent of the sales value of coal produced and sold. However, the coal interests are rather strong in the Legislature this year with the result that there will be no landslide for the interests that are endeavoring to shackle Kentucky operators with a tonnage tax. On Jan. 22 an effort in the House to give the farmer interests a large representation on the House Committee on Taxation and Revenue was defeated, by 64 to 33, in spite of efforts of the opposition to show that the committee was loaded with men favorable to the coal interests.

It was reported from Harlan, on Jan. 20, that the **R. Brown Coal & Coke Co.** had taken back its lease and operation rights sold some time ago to the Standard Harlan Coal Co., because of default in payment of \$25,000 due on the purchase price, along with interest. The property is on the Kellioka seam and was sold to the Standard for a reported price of \$75,000.

The **New Arjay Coal Co.**, Arjay, capital \$40,000, has been chartered by L. A. Bowling, W. B. Landrum and C. F. Wheeler.

The **Cowan Creek Coal Co.**, at Ice, Ky., which is controlled by Cincinnatians, recently installed Jeffery motors, and a new tramway which will increase the output of the mines ten cars a day.

A receiver has been named for the **Harlan Co-Operative Coal Co.**, operating 1,000 acres of coal property of the Darby by-product seam.

MASSACHUSETTS

Fuel Administrator Eugene C. Hultman in a communication to the mayors of cities and boards of selectmen in towns throughout the state urges that wherever the retail prices of anthracite appear to be unreasonable, the local authorities take immediate steps to bring about a reduction, by calling conferences with local dealers. He calls attention to the law cited by the Joint Special Coal Investigating Committee in its report, which gives the local authorities broad powers to regulate the retail coal industry. Mr. Hultman states that the retail price has decreased in a number of municipalities, owing to the drop in independent mine prices, the open winter and the accumulation of stocks by the local dealers.

On Jan. 1 there were 500,000 tons of anthracite in Massachusetts, and the movement into the state since that time has been normal.

Coal dealers of Greater Boston on Jan. 16 reduced the retail price of anthracite to \$15.50 a ton for egg, stove and nut sizes and \$12.50 for pea size. The new prices represent a cut of 50c. a ton. According to the dealers, the reduction was a result of the open winter.

MISSOURI

Fire of incendiary origin last week destroyed the tippie at the **Pierce Hess mine** near Bevier. About 100 men are out of work temporarily. The management of the mine changed hands Jan. 16, when H. B. Pierce sold his interest to Lewis Larsen, of Prairie Hill.

NEW YORK

Harry M. Taylor, president of the United States Distributing Corporation, says that because of the slight decline in the steam prices of anthracite and a corresponding advance in oil prices within the last month a number of plants in New York and vicinity which had been experimenting during the summer months with oil now are changing back to coal. He said that in the main they had found the experiment costly and unsatisfactory.

The Board of Directors of the **Pennsylvania Coal & Coke Corporation** on Jan. 22 declared the regular dividend of \$1 per share out of the accumulated earnings and surplus of the company, payable on Feb. 11. The gross earnings of the company and its subsidiaries for the twelve months ended Dec. 31 amounted to \$8,395,228, as against \$4,996,391 for 1922, and the net income, after charges but before federal taxes, was \$750,793, comparing with \$622,886 for 1922. The income account of the corporation shows gross earnings for December of \$519,098, as compared with \$676,838 for that month in 1922.

Announcement has just been made that the **Brazilian International Centennial Exposition**, recently held at Rio de Janeiro, has awarded the grand prize to E. I. du Pont de Nemours & Co. for its exhibit of dynamite, caps and fuse. The award is especially noteworthy in view of the fact that the du Pont exhibit won the grand prize in competition with products of the same type exhibited by other manufacturers.

Albert McColgan, sales agent of the **Pittsburgh & Ohio Mining Co.** at Buffalo, who has been with the company for seventeen years, has resigned his position, because of ill health. He was formerly connected with the trade at Detroit. His successor is Carl Fraser, who has for some time been his assistant.

The **Virginia Iron, Coal & Coke Co.** reports for the last quarter of 1923 a net income of \$75,371, equivalent, after the deduction of the preferred dividends, to 12c. a share on the \$10,000,000 common stock. This compares with a net income of \$170,413, or 1.07 a share on the common stock, for the preceding quarter, and a net revenue of \$114,984, or 52c. a share, for the second quarter of 1923. The net earnings for the twelve months ended Dec. 31, subject to inventory adjustment, were \$604,328, as compared with net earnings of \$561,983 for the year 1922.

The listing on the New York Stock Exchange of the 1,400,000 shares of no par value stock of the **Philadelphia & Reading Coal & Iron Corporation** has been approved by the Board of Governors of the exchange. The governors also approved the listing of the \$31,542,300 refunding mortgage 5 per cent bonds of the same company, due Jan. 1, 1973; also Reading Co. \$63,084,700 general and refunding mortgage 4½ per cent gold bonds, series A/, due Jan. 1, 1997.

OHIO

The friendly receivership of the **Maynard Coal Co.**, of Columbus, which was brought about recently by interested parties in order to preserve the assets of the company is progressing very satisfactorily, according to George H. Barker, one of the receivers and also vice-president of the corporation. Frank L. Stein, president of the Ohio National Bank, is the other receiver. Lack of funds, due to overproduction is given as the cause for the receivership. The assets are estimated at \$4,833,000 while the liabilities are approximately \$2,000,000. The company holds extensive dock properties at Duluth as well as large operating mines in the Pomeroy Bend field of Ohio and in the Hazard field in Kentucky. The company's annual production capacity is 1,250,000 tons.

The Nelly Coal Co., Macksburg Village, has been incorporated with a capital of \$10,000 to mine and sell coal. Incorporators are Elmer Hostetler, A. D. Kline, C. M. Dilley, H. E. Schulteis and George J. Ackerman.

The Hope Coal Co., Cleveland, has been chartered with a capital of 2,000 shares, no par value, designated to operate coal mines and sell coal and coke. Incorporators are C. H. Juddins, George R. Blackburn, C. G. Collins, Paul R. Brown and Hiland B. Wright.

Receivers for the Lexi Coal Co., Columbus, won their case in the Ohio Supreme Court when the receivers for the Ohio Consolidated Coal Co. attempted to have a judgment for \$32,000 against the Lexi Coal Co. for alleged breach of contract affirmed. The Court of Appeals had reversed the lower court and the Supreme Court affirmed the reversal.

Circuit Court Judges L. E. Knappen and A. C. Denison and District Judge A. M. J. Cochran at Cincinnati on Jan. 18 denied the petition of the Buckeye Coal & Railway Co. and the Sunday Creek Coal Co. of Ohio, asking that the 2c. per ton royalty on coal mined on certain lands conveyed by the Hocking Valley Ry. Co. as security for a mortgage be enjoined. The petition also asked that the lands of the Buckeye company be released from the mortgage given by the Hocking Valley Railway Co. to the Central Trust Co. of New York. The supplemental petition of the United States asking release of the lands of the Buckeye company from the mortgage lien and discharge from paying the royalty also was dismissed. Both the government and the Buckeye and Sunday Creek companies charged that the continuation of the royalty provision of the mortgage was in contravention of the former decree of the court, ordering the dissolution of the so-called coal trust.

Bids were received by the Board of Purchase of the City of Columbus, Jan. 23 for coal to be delivered before March 31 in the following amounts: 5,000 tons of nut, pea and slack for the Municipal Light Plant, Boblo Coal & Sales Co., Pittsburgh, \$1.35, and the Gene Miller Coal Co., of Columbus, \$1.40; 3,500 tons of nut, pea and slack for the Water Works Department, Boblo Coal & Sales Co., Pittsburgh, \$1.30; Gene Miller Coal Co., Columbus, \$1.40; 2,000 tons of nut, pea and slack for the Garbage Disposal Plant, Boblo Coal & Sales Co., of Pittsburgh, \$1.25, and the Gene Miller Coal Co., of Columbus, \$1.40; all bids are f.o.b. mines.

PENNSYLVANIA

The board of directors of the Central Pennsylvania Coal Producers' Association and the executive committee of the Association of Bituminous Coal Operators of the district held meetings Jan. 25 at the headquarters in the Lincoln Trust Building in Altoona and the decision was reached to enter into a general investigation of freight-rate schedules as they affect the district. No action was taken on the question of the coming wage conference with the United Mine Workers, although there was some discussion of the situation. A general meeting of the operators of the district will be held about March 1. The two boards received and accepted the resignation of John S. Sommerville and elected Edgar W. Tate of Pittsburgh, president of the Allegheny River Mining Co., to succeed him on the boards. Mr. Sommerville resigned his official connection with the Rockville Coal & Iron Co. and is locating in New York. President B. M. Clark, of Indiana, presided at the meeting, and others in attendance included Harry Boulton, John C. Forsythe, W. R. Craig, M. J. Bracken, James W. Cook, Rembrandt Peale, H. B. Scott, C. B. Maxwell, E. W. Robertson, J. William Wetter, G. Webb, Shillingford, A. M. Liveright, William Leamont, W. G. Calkins, F. D. Lambert, J. R. Caseley and R. H. Sommerville.

Governor Pinchot has announced that the thirty bituminous inspectors have followed the example of the twenty-two anthracite inspectors and have agreed to take a month's "leave of absence" without pay. In reality this means they will work during this period of a month without compensation, running the risk of getting the \$400 a month allowed by the state at a future date. The lay-off is occasioned by lack of funds in the State Department of Mines, whose appropriation for 1923-1925 was severely cut by Governor Pinchot.

Hyman Michaels Co., Chicago, dealers in new and relaying rails, have placed Al Michaels, assistant treasurer, in charge of their Pittsburgh offices. Mr. Michaels formerly was located in Chicago.

The following officers have been elected for the ensuing year by the Wilkes-Barre Mining Institute: John B. Tamblyn, president; J. S. Hammonds, Edward Flynn and Edward Griffith, vice president; F. M. Devendorf, secretary and treasurer. New members elected on the board are: Paul Warriner, of Lehigh Valley Coal Co.; Thomas Gambold, of Lehigh & Wilkes-Barre Coal Co.; E. S. Morris, of the East Boston Coal Co. and Henry Nothoff of Haddock Mining Co. A speakers' committee was appointed to arrange a program for the banquet to be held in Irem Temple Jan. 30.

The Lehigh Coal & Navigation Co. has awarded the contract for erection of a new breaker to supplant the present one at Lansford. The plant, which will be a steel and concrete structure, will involve an expenditure in the neighborhood of \$1,250,000. Work will be started in the early summer and the new plant is expected to be in operation in the early fall. During the course of construction the present breaker will be operated since the site for the new structure will be east of the old one. The capacity of the new plant will be about 5,000 tons of prepared coal daily. The plans call for a structure similar in design to the present Coaldale breaker.

The convention of the United Mine Workers of District No. 2 will be held in Altoona, March 11. This is the first time in many years that the convention has been held outside of DuBois. So far as the local district is concerned, no schedule of demands has been arranged. Work in District No. 2 has been in bad shape for the union workers, and operators have been suffering with them. What demand there has been for coal in the union section of the district has been supplied by working the men of some of the mines on part time, while many of the smaller operations have been closed entirely. If the convention in Indianapolis can present a plan which will improve conditions in the mining industry in central Pennsylvania, it will find a hearty welcome in this field both by the miners and the operators.

Joseph Linden, who for many years was mine inspector for the Carnegie Coal Co., Pittsburgh, has been appointed general superintendent of that concern, to succeed G. F. Osler, who resigned to become vice-president of the Pittsburgh Terminal Railroad & Coal Co.

VIRGINIA

W. W. Houston, coal broker and former manager for the Pan Handle Coal Co., Norfolk, has been elected chairman of the industrial committee of the Norfolk-Portsmouth Chamber of Commerce. Mr. Houston was chairman of the committee which last year raised a \$1,000,000 industrial revolving fund in the two cities.

WEST VIRGINIA

As the result of a conference held in Huntington on Monday, Jan. 21, between R. M. Lambie, chief of the West Virginia Department of Mines, W. J. Parker of the Pennsylvania Bureau of Mines, and H. E. Mathews, secretary of the Huntington Chamber of Commerce, it has been announced that the seventh annual International First-Aid and Mine-Rescue Meet will be held in Huntington, Sept. 11, 12 and 13. Arrangements will be begun immediately. Widespread interest is being evinced, which it is believed presages a large attendance and the sending of teams from many different sections of the country as well as from other countries.

A charter has been granted to the Mine-to-Consumers Coal Co., of Martinsburg. This concern is capitalized at \$25,000. Its incorporators are Solomon J. and Reuben Fine of Martinsburg; Nathan Fine, of Hancock, Md. and Harry Fine of Baltimore, Md.

In connection with the ejectment suits filed by the Francois Coal Co. against 19 miners formerly in its employ for the possession of company houses, Magistrate R. E. Kidd rendered a decision for the plaintiff in each of the 19 cases, in which the miners had signed written contracts with the company regarding possession of the mine houses. Only about 10 of the miners are affected as a number have already relinquished possession. Counsel for the United Mine Workers has taken an appeal to the Circuit Court of Harrison County. The Antler Coal Co.'s suit against several miners in its employ at Lumberport, in Harrison County, also has been tried and decision reserved.

According to figures compiled by the Kanawha Operators Association, 103,834-

836 tons of coal was produced in West Virginia during 1923, December tonnage in some instances being estimated. The N. & W. Ry. handled 28,818,430 tons of the state's output, and the C. & O. 28,831,600 tons. Transportation of 7,273,375 tons by the Virginian Ry. and of 4,533,981 tons by the Kanawha & Michigan brought the total production of southern West Virginia mines up to 69,557,386 tons. In the northern West Virginia field proper there was an output of 27,827,450 tons, supplemented by an output of 5,200,000 tons in the Northern Panhandle and 1,250,000 tons in the remaining districts of the state. It is shown by the association that 76,057,677 tons or 73.3 per cent of the total output, was produced at non-union mines, as compared with only 34.6 per cent of 92,047,487 tons produced in 1920.

W. E. Deegans and associates of Huntington have sold the New Pocahontas Coal Co., operating at Deegans, in McDowell county, to a group of southern West Virginia operators who have organized the Monarch Smokeless Coal Co. The deal follows closely upon the sale of the Deegans properties in the Logan district to the George M. and Herbert Jones interests. The new company formed to take over the company is capitalized at \$400,000. Such well known coal men as W. D. Ord, of Land-graff; James Elwood Jones, of the Pocahontas Fuel Co.; John J. Lincoln, of Elk-horn; Frank S. Easley, of Bluefield; I. J. Rhodes, of Welch, and Captain D. H. Barger, of Shawsville, are interested in the newly organized company. Included in the transfer were 1,350 acres of fine coal land, this lease representing a merger of the Atlas and Pando leases, a part of the lease running for a period of 20 years or more. The New Pocahontas company had been operating for a period of about eight years in McDowell and had one of the best plants in that section. Mr. Deegans and his associates still maintain their interests in the Margaret Coal Co. and the Frances Coal Co. now engaged in developing smokeless coal properties in the Greenbrier field on an extensive scale.

WASHINGTON, D. C.

Bids are being opened today (Jan. 31) by the U. S. Navy Department for transporting the following tonnages of Navy coal from Hampton Roads in vessels of American registry: On Feb. 12, 3,500 to 5,000 tons to the Portsmouth (N. H.) Navy yard; Feb. 25, 3,500 to 5,000 tons to the Boston Navy yard, and on Feb. 18, 3,500 to 10,000 tons to the Melville (R. I.) Naval fuel depot.

Bids will be opened by the U. S. Navy Department on Feb. 6 for furnishing and delivering at Sewalls Point 40,000 gross tons of bituminous coal from mines on the Navy acceptable list. Total delivery is to be completed by April 1.

CANADA

Premier Ferguson has returned to Toronto after a conference in Ottawa with Sir Henry Thornton and other C. N. R. officials, who assured him that they would reopen the question of freight rates on Alberta coal to Ontario points. The plan suggested involves a rail and water haul, instead of an all-rail haul, from Alberta. It is believed that the government is considering the advisability of transporting coal by ship from the head of the lakes to Toronto and distributing it from there to the various centres of southern Ontario. Shipments for more northern points could be landed at Parry Sound, Midland and other points on Georgian Bay.

The year 1923 was one exceptionally free of fatal accidents in the coal mines of British Columbia. Had it not been for the disaster of last February in the Cumberland Mines of the Canadian Collieries (D), Ltd., Vancouver Island, the record would have been so low as to stamp the year as one of the most gratifying in the history of coal mining in the province. As it is, in many respects the year stands alone. The Crow's Nest Pass field was free of fatal accidents, which, according to the records had never before been achieved. Neither were there any fatalities in the Nicola-Princeton field. Vancouver Island was not so fortunate, but some of the collieries in this field have a clean record in this regard. The Extension Collieries of the Canadian Collieries (D), Ltd.; the Nanose Collieries and the East Wellington Colliery Co. are those ranking in this class. William Sloan, Minister of Mines, forwarded congratulatory messages to the collieries which have been without fatal accidents at the close of the old year.

New Equipment

Lightweight Welder for 500-600 Volts

This lightweight resistance arc welder for 500-600 volt direct-current service is virtually an enlarged model of the Ohio Brass Co. 250-volt machine, with slight modifications necessary for the higher voltage.

It is made portable, having four carrying handles that fold down out of the way when not in use. The machine without accessories weighs only 170 lb. It can easily be conveyed to a bond welding job and then transported as the work progresses. It also can be used for various other jobs around the repair shop and mines.

Plug connections are used on the ebony asbestos panel board for both the trolley cable and welding connections. A magnetically operated switch, enclosed inside the frame, is connected to make contact when the electrode touches the work. It opens as the arc is broken. A pushbutton snap switch adjacent to the electrode handle is provided for completely de-energizing the magnetic switch-closing coil, thus making the electrode absolutely dead.

With the snap switch open safe replacements of electrodes may be made and the electrode may be handled without danger of accidental ground. The magnetic switch is connected into the line on the trolley side, so that when it is open all parts of the machine are dead except for the one connection from the trolley plug socket to the top of the switch. With this assembly it is never necessary for the operator to operate any knife switches on the 500-volt cir-

cuit except when they are completely de-energized.

The frame is of a substantial welded construction and affords ample ventilation for the resistance elements. The resistance consists of nickel-chromium wire rigidly supported in special refractory cement, and will not sag. These resistance elements are joined in such a manner that with the three selective single-pole knife switches and two welding cable connections, 14 values of welding current are available—from 30 to 210 amperes. The resistance units are insulated from the frame with mica tubes and washers.

Actually this welder will operate efficiently on voltages as low as 400 and one of the welding plug connections provides for cases where the voltage is comparatively low. Regular welding accessories are provided with the welder, such as welding cable and electrode, operator's helmet, wire brush and trolley contact and cable. A slow burning fuse is furnished in the trolley contactor, the time element being such that the current will be entirely cut off before damage is done to the machine.

Portable Recording Instrument of Great Accuracy

Among the recent developments by the Westinghouse Electric & Mfg. Co. is a new portable recording instrument known as Type R. It is made for applications where records as accurate and reliable as those obtained with large switchboard instruments are necessary. Such applications include analysis of

Portable Recording Wattmeter

This meter is one of a new type designed to give greater accuracy in testing, including as a new feature an electric self-winding clock mechanism.

motor operation, typical consumption curves of large industrial consumers, and records of power distribution.

The Type R instrument is an adaptation of the switchboard recording instrument, with the element as a whole mounted in a portable carrying case. An electric self-winding clock is used for speeds up to 24 in. per hour. For slower speeds, up to 4 in. per hour, a hand-wound clock can be used.

Alternating-current ammeters, alternating- and direct-current voltmeters, and single and polyphase wattmeters are made in these portable recording instruments.

To Prevent Slippery Floors

To prevent slipping and at the same time add durability to floor surfaces, the Abrasive Co., of Bridesburg, Philadelphia, Pa., has developed Sans-Slip, an abrasive in loose granular form especially adapted for combination with cement. This is an aluminous oxide material quite similar in character to that used in the manufacture of grinding wheels. The angular formation of the grain presents sharp fractures which readily bond with plastic cement and consequently prevent slipping. The material, it is asserted, ranks between the diamond and sapphire in the scale of hardness, which gives some idea why cement laid with it resists wear to a considerable degree and largely prevents "dusting" of the surface.

The application of Sans-Slip in cement work entails no extra labor to speak of. Before the final set of the top surface of the cement, it should be sprinkled over the surface and lightly troweled in. For ordinary non-slip and durability purposes from $\frac{3}{4}$ to 1 lb. per square foot of surface is sufficient. One pound equals about 14.5 cu.in. Its specific gravity is about 3.8. It has pronounced surface capillarity qualities but is non-absorbent; causes no discoloration after it is applied, and can hardly be detected with the eye.

Welding Outfit for Mine Repair Work

An important safety feature—always essential on high-voltage welders—is a magnetic switch to cut off the current when renewing electrode or changing the welding current.

Number 6

On the Keeping of Good Company

ANTHRACITE operators would do well to get out their musty copy books and read what is said as to the desirability of keeping good company, for a person is known by his associates, and if they betray him by their behavior no rectitude of the individual can possibly save him from censure and public reprobation.

The older companies of the anthracite region employ perhaps 1,000 persons to inspect their coal. They maintain their standards year in and year out. When the public can be induced to accept any coal not actually fireproof these companies, nevertheless, maintain their standards, sometimes at a considerable disadvantage because the condemnation of coal by their inspectors means running the coal back through the breaker and interfering with the flow of fresh coal from the mine.

Similarly the larger companies resist the opportunity to sell coal at the market price. When other concerns are making big profits the company coal is sold at the circular rate. The public may bid high, but, undisturbed by such possibilities of abnormal profit, the rates of the larger companies are unchanged except to accord with such variations as occur in the wage scale.

However, the public still condemns the anthracite industry for selling fire-proof coal at fancy prices, and the industry will not be able to avoid the aspersion unless it cleans house of all those who are guilty of dishonest practices. Honest men cannot mix with dishonest and retain a good name. Certainly honest coal and dishonest coal cannot be sold from the same bin by the same dealer and not bring dishonor on the man who provides the clean coal as well as on the man who has provided the fireproof article.

The anthracite industry cannot hide this fact from its eyes. It must drive out dishonest coal—coal loaded unwashed from rock piles, coal improperly cleaned after coming from the mine.

Seeing that one anthracite operator cannot compel another to clean his coal it is necessary or at least advantageous to get the U. S. Government to provide the necessary inspection. It would be costly for the federal authorities to do this properly. The U. S. Bureau of Mines could not afford to hire men to inspect every car of coal coming from the anthracite region—it would take a small army of 1,000 men—but every company could continue its own inspection and the federal tests could be supplementary and most diligent with those individuals who have no inspectional force of their own and who showed a disposition to put poor coal on the market.

The police force shows little interest in the conduct of reputable citizens and quite a keen desire to know what the crooks are doing. The U. S. Bureau of Mines would put most of its effort where it is needed—with the crooked fly-by-nights who buy a culm bank and not a washer or who erect a washer that merely pretends to clean the coal.

With the Bureau ready to fix the rating of any company according to the quality of the coal produced or ready to refuse to give its approval to coal that was below certain standards, the probability is that the companies would employ more inspectors rather than less and the result would be a more uniformly good product.

There are many difficulties, doubtless, and the plan is conceded to be only roughly outlined, but the anthracite companies should get behind some plan for putting the industry on a high plane. They should not so much be advocates of a high standard for any one company, though that is important, but rather press for a general high level that would clear the industry of fraud and deceit. Till that is done the public will laugh at propaganda and say: "Read their high sounding professions and burn their coal—if you can."

Let There Be Peace

A SENSE of injustice pervades the union mining field. The scales in the non-union regions prevent many union mines from working. Unfortunately, no lower wages can help that situation, for competing non-union fields can get a little lower scale merely by asking it—without asking it—if the union regions should obtain a reduction. Consequently a lower wage scale would not help matters.

Furthermore, owing to unsteady work, the miners are not making any too much money the year around with the wages they now have. The cost of living and the rising wages of others also do not favor a decrease in wage. Consequently a wage reduction does not seem possible.

The public would not stand for the profiteering that would follow a strike nor for any increase of price due to a wage advance, so a change in wage either way would be extremely unpopular. After all, in a democratic country we have to be bound by public sentiment, whether just or not, whether satisfactory or deplorable.

Mr. Lewis and his henchmen are taking the right course. Any opposition to their stand for the present wage would be looked upon as an incitement to strike and would bring public reprobation on those who attempted it, whether miners or operators. Let us keep the hands of Congress off the industry by going quietly about our business, lest the public try to make it theirs.

Whether Secretary Hoover is right or wrong in trying to induce the mine operators of western Pennsylvania to attend the meeting at Jacksonville, Fla., as expressed in his letter to C. J. Goodyear, acting commissioner of the Pittsburgh Coal Producers' Association, Jan. 26, certain it is that he is right in saying we should try to get a settlement with the union and that the sentiment of the public is not favorable to a suspension with all that it means to the common welfare.

The story of the negro whose lawyer said he "could

not be jailed for that" and who, being already in jail with the doors locked on him, answered convincingly "But, here I is, boss; here I is," certainly is in point. We may prove our case to our own satisfaction. But the public, what does the public think, and what may the public do? The answer may have to be "But, here I is, boss; here I is," if a suspension ensues resultant on an ill-advised action of the operators or miners.

Complete Mechanization

SO LONG as the "worker" really has to labor and not merely direct the forces of nature to do his work we shall find slackers. So much work is today directional and not actual that the "man with the hoe" is disappearing. The time is coming when we shall say as we arise in the morning not "What must I do today?" but "What must I make steam, electricity or compressed air do for me today?" Time will make us all masters of machines, and what unrelenting masters will we be! We will set the governor, and our machine will do to a turn just what we have determined. We will run the motor at the speed for which it is planned. We will load the belt with all it will carry away.

We shall not slack, for we will be masters and not men. The psychology of the laborer often is to shirk but the idea in the mind of the master is to drive. How evident in the past has been that passion! Mechanize thoroughly, therefore, till all are drivers and none, or at least few, are among the driven. The day of the piece worker nears its end, for the machine will set the pace and not the man. The wage will depend not so much on the industry of the workman as on his intelligence, inventiveness and capacity for management. Complete mechanization will speed that happy day.

Here If Anywhere

GOOD management has made the large central-station power plant triumph in places over the isolated station though the latter has a considerable advantage at the mines. There, if anywhere, it should be possible to wage a successful competition against the encroachments of purchased power. At the coal mines no freight charges on the fuel have to be met, the inferior unsaleable coal can be utilized, plenty of water can frequently be obtained for cooling purposes, space can be found for impounding water and for all the other needs of a power house large enough for a mine.

It is easy to see why the isolated station fell before the onslaughts of central stations in cities where space was at a premium and boilers and engines had to be sunk into basements and buried a hundred feet underground. It can be readily realized how difficult it was to find space to stock fuel in urban regions, and where condensing water had to be obtained from city mains which led it in from points perhaps fifty miles away it was not difficult to explain why condensing was costly or imperfect and its efficiency low. When to this consideration is added the fact that the fuel must be transported in wagons on city streets or in the case of non-urban installations had often to be unloaded, stored and removed from storage by inefficient and inadequate equipment it is clear that the isolated plant away from the mines had a hard road to travel.

But at the mines the freight, land, water and storage

problems are all as a rule favorable. The central station sometimes has to pay freight and the operator's profit on coal and always has to meet the losses of main-line transmission to the mine and yet has to compete with isolated stations that pay no freight and have only the inevitable local transmission losses.

Nothing but bad management has made the isolated plant give way. Nothing but old-fashioned equipment, meager talent, bad mine management, failure to provide recording gages and a lack of operating statistics has rendered the blandishments of purchased-power salesmen successful. Had the plants been well managed they would have held their own and every now and again, as in this week's issue of *Coal Age*, we read of some fit plant well handled and hear that it more than holds its own.

Its stand is economically sound, as reasonable as that of the farmer. He doesn't take his potatoes all the way to market and buy another sack of spuds to bring back home with him. No, he consumes all the potatoes his family needs and the overplus and the better potatoes he sells in the market, thus saving transportation and distribution charges on his home consumption.

That many operators are not convinced that purchased power pays is evidenced by the report of the U. S. Bureau of Census. As recently as 1919, the stationary motors using purchased power aggregated 889,171 hp. and the aggregate of all the power around the mines was no less than 3,055,195 hp. or almost four times as great.

More Government Monopoly

A REPRESENTATIVE from Dayton, Ohio, R. G. Fitzgerald, has introduced into the U. S. House of Representatives a bill giving the government monopolistic control of workmen's compensation in the District of Columbia. No company, if the bill passes, may be a self-insurer nor may it cover its risks by insuring with any private insurance company. Its advocates hope that this bill will be the opening wedge for legislation of like kind in other states. It is true that seven states and Porto Rico likewise have such monopolistic measures and nine states have provisions under which the state insures those who desire state insurance. The latter, however, permit self and company insurance to compete with the government. Often, despite lower state rates firms prefer company insurance because of the better service afforded by such insurers.

The U. S. Chamber of Commerce is backing the bill introduced by Charles L. Underhill, which permits only of self and company insurance, for it has by referendum definitely concluded to oppose the entrance of the government into business. The backers of the Fitzgerald bill say that no private company should be allowed to make a profit on a matter so vital to the individual of small means as is workmen's compensation.

That sounds somewhat convincing till one reflects that the farmer, the doctor, and a number of persons are making a profit out of the vital needs of individuals of small means.

How far will the government go in the matter of monopolistic business? If this bill is allowed to pass we may find government bureaus, state and federal, monopolizing the main industries of the nation. This is an entering wedge to more than workmen's compensation insurance—a step indeed toward Sovietism in the Republic. The Fitzgerald bill should never be allowed to take its place in the statute books of this nation.

With Hand Shoveling 10 Tons per Man and 26 Tons per Loader Already Attained

One Panel Working 65 Men Will Yield 1,000 Tons of Coal per Day—Portable Conveyors Transport Coal from Face to Heading—Pillar Points Protect Faces and Projecting Roof Against Caves

BY ALPHONSE F. BROSKY
Assistant Editor, *Coal Age*, Pittsburgh, Pa.

ENTIRELY without any prior notification to the mining public the West Virginia Coal & Coke Co. answers conclusively the old question: How can the average daily output per man employed be increased? It has succeeded in increasing the efficiency of labor and in improving the equipment used in the mining of coal. It has concentrated operation and limited the activities of mining to small areas that accordingly are rapidly exhausted.

This it has done by introducing a modified longwall system of mining, by loading coal mechanically and using conveyors to afford a means of continuously transporting coal from the working face to the tipple. It purposes thus to eliminate much deadwork and many delays in mining, loading and transportation. That these changes offer excellent opportunities for reduced expense can be judged by what the company has obtained from them.

In one section of its No. 9 mine at Norton, seven miles from Elkins, W. Va., on the Coal & Coke division of the Baltimore & Ohio R.R., it has already succeeded in obtaining more than 10 tons per man employed for all operations from the face to the railroad car. According to the U. S. Coal Commission the highest daily output per man thus far obtained in all bituminous mines is 4.19 tons as of 1921. Depending upon conditions and with some changes in its new methods

of mining, this company expects, in varying degrees, to increase a miner's daily output to a maximum greater by several times than that now generally obtained.

FACE ARRANGED LIKE TEETH OF CROSS CUT SAW

No. 9 mine originally was opened up for room-and-pillar mining. However, a right section extending north from the main heading to the outcrop, composed of panels set off by cross and parallel headings, is now being won by a modified system of longwall mining. The plan of mining is called the "V" system because the faces constituting the working front of a panel are arranged in points as on a saw. As portable conveyors are used to transport coal from the working faces to the main panel headings and as it is the purpose also to use loading machines, it was decided several years ago that fairly long working faces should be used or the maximum advantage would not be obtained from this equipment.

Experiments have been made extending over a period of nearly three years. In some of these the faces have been laid out perpendicular to the direction of retreat and in others they have inclined at 45 deg. to each other in a saw-tooth front. Experience has proved to the satisfaction of the company that the last-mentioned arrangement of faces is best suited to the conditions that exist in this mine. Nevertheless the working layout should not be definitely fixed but should be modified with such flexibility as to meet with great nicety the varied conditions which other mines may present.

When conveyors are used to carry coal to the railroad, no such complicated structure as the tipple at No. 9 mine of the West Virginia Coal & Coke Co., shown in the headpiece, will be needed. It will be changed to a light timber construction costing about one-seventh as much as an ordinary tipple.

The "V" system proper, as used in this mine and shown in Fig. 1, is developed in the advance by single gallery entries which split the panel into pillars. These are drawn back on an even front, all the tooth points lining up at right angles to the direction of the galleries. Pillar drawing follows closely on the heels of gallery driving and these two practically simultaneous operations may be performed either "advancing" or "retreating," using those terms in a broad sense.

Toward each gallery two faces converge to form a "V" at an angle of 45 deg. As these faces are practically joined one to another, the resulting layout is like the cutting edge of a saw. Each gallery serves as an exit for the coal slabbed off a pair of faces. Single lateral entries are driven at intervals to connect the single gallery entries with a double entry, driven, as is customary, to provide means of transportation and ventilation to the panel. In a 6-ft. seam of clean coal the output per day will be about 1,000 tons.

A panel is 320 ft. wide and about 1,350 ft. long. Galleries are driven 8 ft. wide on 80-ft. centers and intersect lateral entries on 200-ft. centers. The working faces at 45 deg. to each other are about 87 ft. long. Three galleries and one panel entry, which serves the same purpose as a gallery, split a panel into four pillar units of eight working faces, each gallery giving access to two faces.

The length and width of the pillars are not limited to the dimensions already given. Their length is determined by the transportation needs, as in room-and-pillar or any other system of mining, and their width is decided by the length and number of faces desired, remembering that the portable conveyor units are

sectional and can be lengthened or shortened at will.

Only a brief description of the conveyor will be given here, those points being mentioned that are necessary to explain its use in this system of mining. Details and applications of this conveyor will appear in a later article.

The Movor steel pan-belt conveyor is assembled into any desired length by joining sections which are generally 6 ft. long. Each section is composed of two distinct elements, a structural steel frame and a belt of steel pans joined by through axles, to which are fastened carrying wheels. These sectional elements are readily coupled to, or uncoupled from, the end of a conveyor unit.

Each element may be moved independently, and the elements are so light that two men can carry them from place to place. A drive section may be inserted at any point and is sufficient to actuate a 100-ft. conveyor unit. For greater lengths two or more drive sections are necessary.

Each face, gallery and lateral entry of a panel has its own conveyor unit. Face units may be shifted bodily sidewise toward the face or lengthwise to adjust their position relative to the gallery as the pillars retreat toward the lateral entry. In a single panel, eight face conveyors empty in pairs onto four gallery conveyors, which in turn connect with a common lateral conveyor leading to mine cars on the main panel entry.

Retreating faces and advancing galleries, each in adjoining panel blocks, move as a continuous process in the same direction at the same rate. It already has been pointed out that this general direction may be, in the broad sense of the terms, either that of advancing

or retreating. In beginning to develop a panel, after the galleries have been driven from one lateral entry to the other, the faces start to retreat, and the galleries are driven on through the second block of the panel toward the second lateral entry at a rate equal to that of the retreat of the faces in the first block.

A 6½-ft. undercut, which is the depth now being used, will advance the faces 18 ft. in the direction of retreating. This means that as the faces retreat in the first block the gallery conveyors will be shortened 18 ft. each time a cut is made. Each section of the conveyor is 6 ft. long, so three sections are removed from each gallery. These are placed in the advancing galleries of the second block to extend the gallery conveyor units that are employed in their driving.

By the time the galleries in the second block are driven through to the second lateral entry, the first block is finished and the pillars in the second block are started on a retreat. Thereafter the gallery conveyors move toward the second lateral entry. The direction of travel of the conveyors is reversed simply by reversing the direction of the current through the motors. The

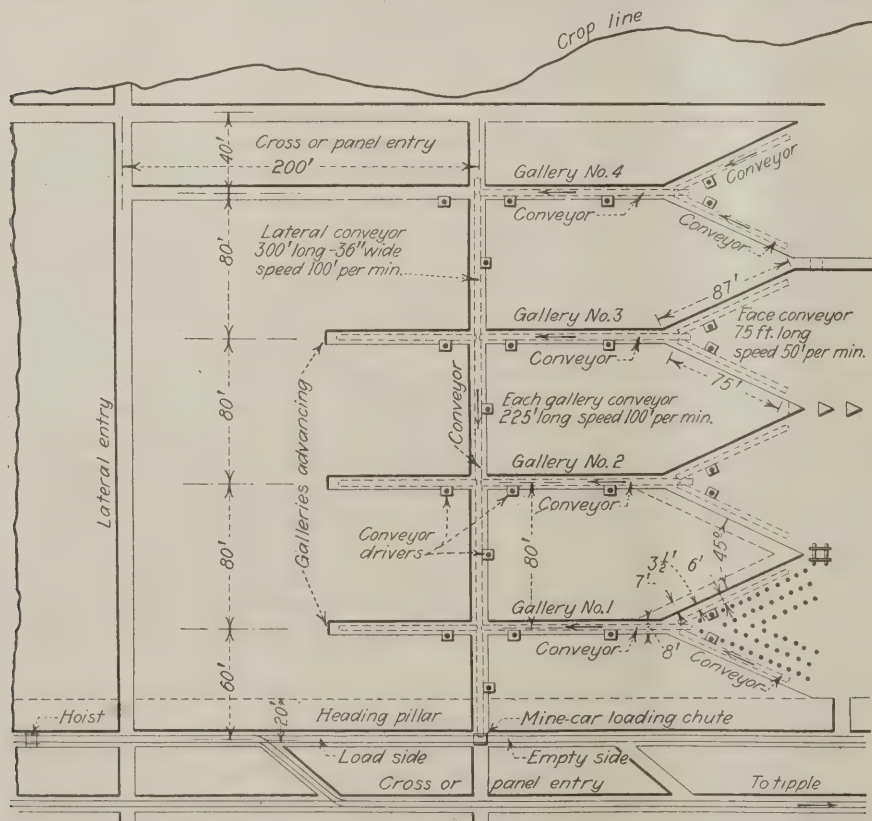

Fig. 1—Working Method, Pillar Protection and Conveyor Layout

When the roof settles it caves, but fall is kept from the pillars by timbers and stumps of solid coal. Conveyors not only take coal away from the faces but are used also in developing the galleries shown. The equipment required is one lateral conveyor, 300 ft. long, four cross conveyors aggregating 800 ft. in length and eight face conveyors of a total length of 600 ft. The aggregate length of conveyor needed is 1,700 ft. On the lateral conveyor are five drive sections, on the cross conveyors eleven drive sections, on the face conveyor eight drive sections, or 24 in all.

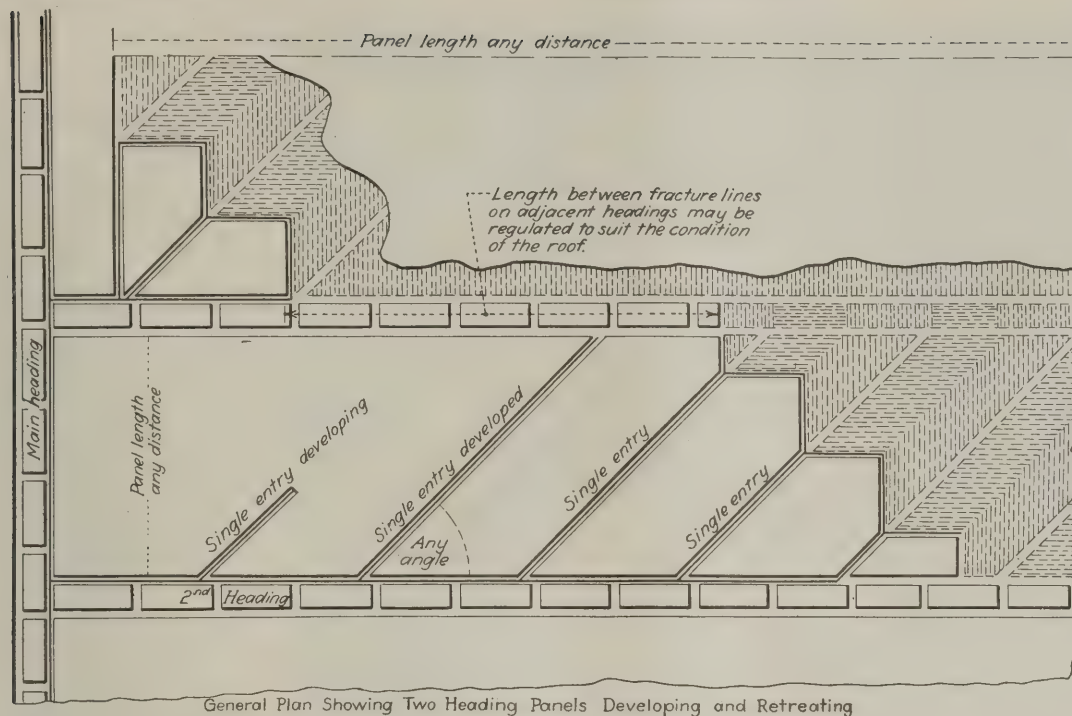

FIG. 2

Another System

Though the angle between the faces in No. 9 mine is 45 deg., that angle may be opened or closed to meet any particular condition. The more fragile the roof, the less the angle between the faces. The length of the retreating faces may be varied to suit the needs of the roof. In each case the point of retreat for the men, if retreat indeed should be necessary, is in a recess in the face well protected on either side by solid pillars.

cycle is repeated until the panel is extracted. The success of the "V" system of mining is dependent on the use of these portable conveyor units, which also may be used in connection with other systems of mining.

A development which would produce only a small tonnage with the room-and-pillar system will with the "V" system afford a large output. Consequently a large tonnage per panel can be obtained in a short time and at low cost. The following account will illustrate this point:

At 5 p.m. on Dec. 12 of last year No. 1 panel in the right section of No. 9 mine reached its mining limit, having been worked to the crop. A panel in another section of the mine had already been prepared for mining by this system. The development that had been done in it consisted of the driving of the customary double entries by which it was flanked, the driving of the first lateral entry and of four galleries. This second panel, as described above, was ready for operation when the first panel was mined out.

Beginning at 5 p.m. on Dec. 12 the conveyors at the faces and in the lateral entry and those in the

galleries of the first panel at the time the latter was completed were moved a distance of 2,500 ft. and set up in the second panel. On the morning of Dec. 14, forty hours later, these conveyors were in operation in the second panel, where eight faces were started off four galleries.

On that day 200 tons of coal was mined. By Dec. 18, four days after starting the panel, the production had grown to 916 tons, the average daily production for the week following that day being 930 tons. Truly that is a remarkable feat—finishing one panel on Dec. 12, moving the conveyor equipment 2,500 ft. to another panel and in one week's time getting out a daily output in excess of 900 tons! This feat probably is without parallel in the history of coal mining.

Within and between the points at the end of two adjoining pillars is an open triangular area, the roof above which must be supported by timbers. Their size and the centers on which they are placed depend, of course, upon the tendency of the roof to fall. Especially is that true under conditions met in No. 1 panel, which was recently completed, where the cover decreases

FIG. 3

Cut Shot Down

Sometimes small lumps roll out and bury the conveyor, but the latter is capable of digging its way out. Note the arrangement of conveyor and timbers with respect to each other and the face. Experience has shown that the timbers need not be as large as those shown in the illustration. At present no timbers are recovered. They are cut with an ax and allowed to break when no longer needed.

FIG. 4

Four Suggested Systems

Here also the retreating faces may be varied so that the roof may be adequately supported. One system in the lower left corner shows a continuous face with conveyors delivering to the gallery conveyors. In the system in the lower right corner the retreating faces are of unequal length, each gallery having one short and one long face feeding coal to it and one face delivering direct to the heading.

from a thickness of 150 ft. above No. 1 gallery to 25 ft. above No. 4 gallery, the latter being near the crop.

Several of the illustrations show rather big timbers for holding the roof, but experience has taught that these are a necessity only under unusual roof and that small props are sufficiently strong for most purposes. Generally a split post equivalent to a 6-in. round post is placed on 3-ft. centers. The last rows of timbers are placed alongside and nearly touching the face conveyors.

Cribs have not been effective as a protection of pillar points in this mine. Being brittle and following the laws of caving, the roof breaks without letting the cribs take the weight gradually. For the same reason packwalls are of little value.

The average depth of undercut, with a 7½-ft. cutter arm, is about 6½ ft. A fall occurs about every four cuts, or every 72 ft. of advance or retreat of the gallery leading to the face. During the first and last cuts of a cycle great care must be exercised to keep the timbers as close as possible to the face to protect men and equipment from dangers incidental to a fall, which, however, never occurs without ample warning.

No attempt is made to recover timbers. At the end of a cycle of four cuts, when a fall is desired, a closely supervised crew of timbermen cut notches in as many of the timbers as possible between the line where the next break is desired and the last fall. In this and other work performed in connection with this system of mining over a period of nearly three years no accidents of any kind to employees have occurred.

When the roof falls it may break at, or encroach slightly on, the saw-tooth point of each pillar. At least that has been the experience in the No. 9 mine. In such cases no traveling way is kept open at pillar points where the two adjacent working faces meet.

One of several schemes may be adopted, as in Fig. 1, to stop the fall from encroaching any appreciable distance past the points of the pillars. The roof may be such that it can be controlled by a "breaker" row of timbers. In that case the recovery is about as near 100 per cent as can be attained by any method of mining. The management anticipates more easily controlled roof in a section of this mine where the cover is thicker and where timbers are expected to hold the roof while practically all the coal is removed.

Nevertheless conditions have been encountered in which the break occurred at or on the points of the pillar. As the roof is hard and fragile, tending to break rather than bend and to cave rather than subside, a protecting pillar frequently is left as a continuation of the points of the main pillar, but the roof does not rest long enough on these to cause a squeeze. This pillar may be solid and narrow or it may be in the form of a chain of square or triangular stumps as indicated in Fig. 1. These latter are formed by cutting through the pillar at short distances behind the point. They afford a convenient passageway between working places. In any case, the coal lost in thus protecting the points of the pillar is but a small part of that recovered and the percentage of recovery consequently is high.

The roof will break in a span of about 80 ft. and will not hang as a body on the protecting pillars. An ideal working condition exists at the faces in that the roof is supported as a beam by the ends of the pillar, aided by the timbers in the triangular space. Within this space, consequently, there is no overhanging ledge, as in caving systems where straight faces are maintained, nor is there a tendency to creep, such as is manifest in the subsidence systems of longwall mining.

More space can be left, therefore, between the last row of timbers and the face, giving ample room for the conveyor and for loading by hand or by machines. Timbers within the triangular space take care of whatever subsidence takes place between the pillar points, and any caving that might occur in the gob is so far removed that it will not menace the men and the equipment at the faces.

The possibility of wide variations is suggested in the length and angle of the faces to meet conditions brought about by various thicknesses of cover and characters of roof. Thus it is pointed out that a tender roof under light cover will allow the working of faces that are longer and joined in a narrower angle than those under heavy cover and strong roof.

Several of these variations are indicated in Figs. 2 and 4. In the main the system is best adapted to work under light cover and tender roof, and experience in other modifications of longwall mining cannot be entirely relied upon in judging the limits under which a successful application can be made.

FIG. 5

Loading Out

A loader has a "cinch" in loading out 25 tons of coal per shift as compared with work in a room, for he does not have to exert himself by throwing coal long distances or to any considerable height. Note how several men work together, making the labor of loading more congenial than when in a room alone or in pairs. Furthermore the most careful man in the crew is sure to see that the place is safe. At least one man is likely to have a "hunch" for timbering, though some may be willing to take chances to see the coal fly.

Let us now turn to the details of the mine work at the face.

The Lower Kittanning seam is being worked in No. 9 mine. Its maximum thickness is 7 ft., but not all the coal is merchantable. About 18 in. above a bottom of hard shale occurs a 6- to 14-in. parting of hard fireclay which splits the clean coal into two benches, aggregating 5 ft. in thickness. Above the upper bench is an 18-in. bed of roof coal that is left in place. Above this is a hard, easily broken and non-flexible shale and sandstone which remain up until a break and fall are desired.

A description of a working place in various stages of mining by the "V" system may aid the reader to visualize actual conditions at the faces. Let us assume that the night shift is so far spent that the face conveyors have been shifted toward the faces and rows of timbers set behind them to make ready for the mining of the next cut. Standing then at the mouth of a

gallery one sees two diverging and long open alleys which are fenced on one side by a row of timbers and about 6 ft. away on the other side bounded by a face of coal.

Nearly touching the former in each alley is a face conveyor 20 in. wide, leaving a working space from 3 to 4 ft. wide between the face and the conveyor, which is sufficient when a longwall machine is used for undercutting. When the face is shot down the coal rolls outward, so that in places the conveyor may be covered with coal. By day one will notice four or five men, one of whom is a "strawboss," at work on each face, shoveling or lifting lumps of coal onto the conveyor.

Immediately after the faces are cleaned up one observes a roof span 11 or 12 ft. wide supported by solid coal on one side and a row of timbers on the other, indicating the depth of cut cleaned up, and showing that there is sufficient width for the use of a

FIG. 6

Shifting Conveyor Towards Face

After each cut the face conveyor must be shifted sideways the depth of the cut and moved in the direction of the gallery a distance equal to the length of three sections of the conveyor. A prop puller does this admirably. The seam is in two parts. The coal is shot and the upper bench removed, the parting of clay is then shoveled over the conveyor into the goaf and then the lower bench is fed to the conveyor.

FIG. 7

Well-Loaded Conveyors

Because this lateral conveyor must dispose of all the coal coming from four gallery conveyors it should be made about twice as wide as the experimental conveyor shown here. In this system entries can be kept tidy at all times. Electric lights make the lateral, the galleries and the faces safer places in which to work.

special type of loading machine. All this can be viewed from the mouth of the gallery, for faces as well as the various conveyor entries are illuminated by electric lamps on a line circuit.

Modern mining must embody the principles which other industries long ago put into practice but which, by reason of the difficulty of application, mine managers are only beginning to utilize, namely, ample illumination, segregation and judicious division of labor and, most important, intelligent supervision as regards efficiency and safety. A crew of ten men or more working together as "buddies" are more cheerful and willing than they are when working alone in one-man places. And rest assured that ten men will not jointly run risks by unsafe practices even though they might do so as individuals.

Longwall mining machines are better than shortwall machines for undercutting the coal because the former require less working space and cut in any direction. Consequently, when the longwall machine is used, the conveyor can be shifted toward the face on the completion of the loading of a cut and a row of timbers placed behind it, leaving a roof span of 6 ft. over the men who do the cutting. When a shortwall machine is used this roof span may be 9 ft. wide.

The two benches of merchantable coal, separated by the clay parting are shot down as a unit. If after shooting the conveyor is partly buried in coal it is capable of digging its way out. The top bench of coal is loaded out first, after which the parting is broken up and shoveled over the conveyor into the gob between the timbers. At least two-thirds of a loader's time is utilized in gobbing the parting, seriously affecting his actual capacity for loading clean coal, for it should be remembered he does not have any time during which he is waiting for cars and consequently whatever time is spent shoveling clay is time lost to shoveling of coal.

Depending on the depth of the cut, four or five loaders are employed on each face. Thirty-two loaders working in a panel of eight faces can produce 830 tons of coal per shift. Forty loaders are expected to produce 1,050 tons per shift. In either case the average output per loader per shift is 26 tons. In a seam of equal thickness, free of partings, the output per loader per shift should be increased to 30 tons or more. At the present time

from 50 to 65 men are employed in a section, the output per man being about 10 tons per day or 1.25 tons per man-hour, for all day and night employees.

It is not to be supposed, with the many savings this system of mining affords, that advantage will not be taken of even greater gain by the use of loading machines. A machine will be developed, requiring not more than 24 in. clearance, that will be light enough and easily moved from place to place. Such a machine will load coal from the end of the pile, its long axis being parallel to the face when loading coal, and will advance from the gallery toward the point of the pillar. Modifications of longwall mining, conveyors, and loading machines undoubtedly will make possible even at the present time the economic mining of some seams 3 ft. thick in competition with mining by other methods in seams much thicker.

In Fig. 1 is shown the general arrangement for transporting coal from the faces to the tippie. As already noted, conveyors carry coal to the loading point, where it is loaded into mine cars. To do this one

Fig. 8—Gallery Boom Feeds Lateral Conveyor

In order to discharge onto another conveyor, the end of the Mover conveyor is curved upward by the addition of a curved section as shown. Coal does not spill at discharge points.

FIG. 9

Lateral Conveyor Loading Mine Car

A chute which is swung as a cradle by a lever diverts the coal coming from the conveyor either into the back end of the mine car shown or into the front end of the one behind it. The switchboard on the left controls the lateral and gallery conveyors and also the remote-controlled hoist by which the mine cars are moved.

man equipped with a rope hoist to move the trips is required. The conveyor is not stopped while the mine cars are being shifted. The trimmer manipulates a lever-operated chute on a cradle axle that causes the discharge of coal to change direction, without spillage, from the rear end of a loaded car to the front end of an empty car.

Directly behind the trimmer is a switchboard, by which he can control the movements of the hoist and the main conveyor. Gallery and lateral conveyors are controlled from the switchboard, which also is arranged to stop face conveyors. The latter, however, can be started only by "straw bosses" and only also when the gallery and lateral conveyors are in motion. The switches for starting the face conveyors are located at the face at a point near the gallery.

A 10-ton locomotive hauls a trip of twenty-five 2.4-ton mine cars to the loading point, where it is uncoupled and run to the storage track, where the loaded trip is standing. This it hauls to the tippie, which is 3,000 ft. distant. The average time of a round trip between those points is 15 minutes. The average time of loading a trip, including incidental delays, is about the same, so the locomotive is on the go all the time. A trip has been loaded in 10 minutes, or at the rate of 6 tons per minute.

Absolute control and continuity of operation of loading and transportation in the panel are assured. Delays are minimized and mine cars are idle only a small fraction of the loading time, each making at least five trips to the tippie in one shift. The company will soon open up a mine in the Upper Kittanning seam, in which conveyors will be used to transport coal from face to tippie. Many savings will result therefrom, for mine-car haulage will be eliminated and no roof will have to be brushed or bottom lifted to make good haulage grades.

Many advantages accrue from using this system of mining instead of room-and-pillar mining. Some of these are self-evident, others have already been elaborated in the preceding text. For brevity I shall set them down without explanation as they were given to me by the company. They are:

- (1) Higher percentage of recovery; (2) no necessity for supporting roof in first mining; (3) better supervision of labor; (4) better and more simplified ventilation and drainage; (5) no abandoned workings where gas and water may accumulate; (6) miners' lamps eliminated by use of electric lighting; (7) no abandoned working places where equipment may be lost; (8) harmony due to psychology of grouped labor; (9) greater safety due to the operation being by groups; (10) no shotfiring during working hours; (11) no explosives handled by inexperienced men.

The advantages over ordinary longwall mining are:

- (1) Miners and equipment are protected on either flank by solid coal; (2) ability to change direction and length of faces; (3) length of working face greater than width of panel; (4) rapid recovery due to angle of faces; (5) entry development without need of mine cars; (6) adaptation to either advance or retreat; (7) quick development possible for new properties; (8) increased tonnage per employee; (9) no tracks or trolley wires near men at working faces; (10) loading operation easier into conveyors than into cars; (11) greater economy in equipment for a given output; (12) greater capacity in a given area; (13) miners not delayed by inadequate transportation facilities; (14) workers less dependent on other operation forces; (15) distribution of labor more flexible; (16) use of light, portable and self-contained conveyors; (17) less possibility of accident by reason of the removal of the haulage hazard.

RESUME STUDY OF MINE EXPLOSIONS.—George S. Rice, of the Bureau of Mines found on his trip to Europe that research into the causes and prevention of mine explosions had been virtually stopped in Europe during the war-time period and had not been fully resumed in Continental countries, except that in France the fundamentals of safety explosives are being studied. In Great Britain, research along this line has been resumed at the Eskmeals experimental station and also at several of the universities. In the study of the use of stone dust English investigators have attained greater progress than that achieved in the United States.

How Output of Men in Mines Varies with Size of Plant, Seam Thickness and Labor Relations

In Some Well Managed Mines Four Times as Much Is Done per Man as in Others—Low Tonnages per Man in Union Mines—Man in Big Mine Has Slightly Larger Capacity

By HOWARD N. EAVENSON

Pittsburgh, Pa.

A STUDY of the data presented in this article will show that with the proper organization and with carefully planned mining methods, the average quantity of coal loaded per day, where this quantity is not restricted by outside regulations, can be increased at least 25 per cent without a corresponding increase in the day labor needed.

The information contained in this article was collected at the request of the U. S. Coal Commission and is published with the permission of that body and of the various companies furnishing the data. For obvious reasons, the names of the companies are not given. No data were obtained from states south of Virginia or west of the Mississippi River.

The data covering the labor, in man-hours, required to produce a ton of bituminous coal have been collected with the idea of showing what is being done at some well-managed plants and not to show the average labor required by all mines, which undoubtedly is considerably higher than the average of the figures shown. Almost all the figures were obtained by a questionnaire addressed to the companies whose records are given. When they were obtained from other sources the com-

Article to be presented at the New York meeting of the American Institute of Mining and Metallurgical Engineers, in February.

In June, 1922, at Mine No. 16 in Logan Co., one man loaded 572 mine cars holding 743.6 net tons coal in 222 hr. spent in the mine. Loader worked in two entries 18 ft. wide, coal averaged 44 in. thick; he drilled and shot his coal, but neither picked out impurities nor set timbers. Roof conditions in these working places were not favorable with considerable water present. Besides this, he did 2 days or 18 hr. of day work; his total earnings for the month, including pay for water at face, were \$528.50. Average loading per hour = 3.4 tons or 2.5 mine cars.

the figures represent in each case a month chosen because the car supply was good and the work was practically steady. In most of the West Virginia and Kentucky mines these conditions were best met in May and June, 1922.

The mines for which the figures are given are arranged by states and as to whether the mine operates under union or non-union conditions. The union and

non-union mines in the list are generally considered to be equally well managed.

The production per month in a few cases includes the slate which has to be loaded and hauled out of the mine, for this needs almost as much handling as coal. Where this is the case that fact is noted.

The number of days worked includes only the total time in which the tippie operated; not the number of days on which the mines ran. This makes the output per day appear slightly higher than it should be in these cases, but does not affect the item of "days worked," as the total days worked per month for each class, or the average number of each class working

TABLE III (CONTINUED)—PRODUCTION DATA, KENTUCKY MINES

Mine	Can Loaders Produce More with Full Car Supply?	Remarks
1		Loaders with exception of machine, load drill and shoot coal
2		All loaders timber, lay track and clean dirt
3	Yes	Same as No. 1
4	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
5	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
6	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
7	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
8	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
9	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
10	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
11	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
12	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
13	Yes	Loaders drill, timber, lay track and clean dirt; do not shoot
14		Loaders load only, but clean 8-in. laminated coal.
15		Loaders timber and lay straight room track only
16		Loaders timber and lay straight room track only
17	Yes	Loaders drill, clean coal, set timbers and pay for one-half shooting
18	Not this month	Loaders drill, clean coal, set timbers and pay for one-half shooting
19	Yes	Loaders drill, clean coal, set timbers and pay for one-half shooting
20		Loaders drill, shoot coal, timber, but do no track work
21		

Working time was 8 hr. per day. In addition to loading coal, the loader only lays "jumpers" in the face of his room. Drilling, shooting, timbering and straight track work is done by the company. Loader E earnings, in month given (January, 1921) were \$547.80.

per day, were reported. It is hardly likely that any error introduced by this factor will be as great as the variation in production is from month to month, even at the same plant.

The number of machine men working per day includes both machine runners and helpers, and in computing the average production per day, the number of crews, each of two men, is used as the divisor and the number of man-hours per ton includes the time of

both men. The coal produced per machine sometimes includes all coal produced, both pick and machine, as data were not always available for separating this. Wherever it could be segregated, it is so shown and computed.

The number of man-hours per ton is computed from the actual number of hours in the working day at each plant and not from the time actually spent at the face. Usually the loader does not stay at the face all

8		Loaders drill timber and lay track
9		Loaders lay track and set timbers
10		Loaders drill, shoot coal, timber and lay room track
11		Loaders drill, shoot coal, timber and lay room track

At Mine No. 9, in Fayette County, pick miner loading average for past years is 11 net tons daily; loader average after air-puncher mining machine is approximately 17 net tons per day; loader average after electric shortwall, mining machine is approximately 20 net tons per day. Pick miners lay track, set timbers and drill holes; machine loaders lay track, set timbers but drill no holes—neither class handles much slate. Roof coal or draw slate are left up in working places. Empty cars are delivered to the face of working places.

the time that the mine works; in most mines the actual time at the face does not average over seven hours. All labor required in producing coal is included in the figures, whether employed inside or outside. The figure in the column headed "Greatest tonnage loaded in one day" is the largest quantity loaded during that month.

In the accompanying tables the figures under total labor are not the sums of figures in the previous columns; each item is the minimum or maximum of

the figures in its class. For all the mines given the data can be summarized as shown in Table I.

The production per loader in mines Nos. 9 and 27 is the average production of thousands of men in different states and in many mines under different conditions. There is no doubt that this rate can be equalled in nearly all mines with approximately the same coal thicknesses, and it should be excelled in many mines with better roof conditions.

In comparing the day labor required in the Illinois, Indiana and Ohio mines with those in eastern Kentucky, West Virginia and Pennsylvania it must be remembered that pillar withdrawal is practically unknown in the former three states, though largely practiced in the latter ones.

Estimates show that in the latter mines the inside day labor could be reduced from 25 to 50 per cent, which would affect not only the slate, timber and trackmen but the men engaged in transportation, if the same methods of mining were practiced. This increase in day labor required for pillar withdrawal is, of course, balanced against the increased yield of coal per acre.

If all of the best performances could be grouped at one plant it would be possible, by present methods,

State†	1.40		1.54	2.71
State†	0.86	0.08		1.78

† Second set of figures for each year include mines from Districts 1, 2, 3, 4, 5, 6, 7.

Note—The unit figures for 1920 are all slightly higher than the actual figure, as, the tonnages include some mines not reporting the days worked. All base data from coal operators' associations' bulletins.

District 1.—No. 2 seam is worked almost entirely by longwall, pick miners in small shaft operations that could not compete with the rest of the state if they were not so close to Chicago. The seam is from 2 ft. 6 in. to 4 ft. 0 in. thick, averaging about 3 ft. 4 in. and has irregular streaks of dirt and sulphur in it, as thick as 4 in. Roof conditions are poor. Grades are slight in most of the district.

District 2.—No. 1 seam averages 4 ft. thick and is much broken by small faults, slips and clay veins. It has numerous sulphur bands locally. The roof is usually good, the fireclay bottom heaves badly when wet. No. 2 seam, is the same as in District 1. No. 5 seam is from 4 to 8 ft. thick, averaging 4 ft. 8 in., with discontinuous bands of pyrites over the middle of the seam. The gray fireclay bottom heaves badly when air slaked. In local sections, a thin layer of iron pyrites on top of the coal keeps the roof up.

District 3.—No. 5 seam is the same as in District 2. No. 6 seam averages about 6 ft. thick and has a band of iron pyrites about 2 in. thick, in the lower part of the seam. It has a hard clay bottom and a shale top that disintegrates with exposure.

District 4.—No. 6 seam is about the same as in District 3 and furnishes nearly all the production in this district.

District 5.—No. 6 seam is about the same as in Districts 3 and 4, except that the roof is always shale and falls easily; the bottom is soft fireclay. No. 7 seam is from 2 ft. 6 in. to 7 ft. 6 in. thick and averages about 5 ft. 6 in. It contains numerous bands and lenses of sulphur. The roof, not generally good, is a black shale; the bottom is soft fireclay. The two seams share in the district's production.

District 6.—No. 6 seam supplies almost all the production in this district and averages about 7 ft. thick. It has a quantity of impurities. Its roof and bottom are as in District 5.

District 7.—Normally District 7 supplies about 40 per cent. of the state output. No. 5 seam averages about 4 ft. 6 in. thick with, usually, a good roof and bottom. The quality of this coal is best in this district. No. 6 seam reaches a maximum thickness of 14 ft. varying from 8 to 12 ft. over large areas. It always has the parting of iron pyrites; in the thickest coal that parting is sometimes 4 in. thick, and while the top is not good, usually a foot or more of coal is left up for support. This district has a number of large mines, some of them the largest producers in the world.

to produce a ton of coal with 0.644 man-hour of labor, or slightly less than 77 per cent of the best total figure shown by these data.

GEORGE OTIS SMITH, Director of the Geological Survey states that activities in which topographic maps are essential are mining operations, and oil and water power development. Co-operative topographic mapping with the Geological Survey has been requested by states for the following purposes: California, oil; Colorado, coal; Idaho, phosphate; Kentucky, oil and coal; Louisiana, oil fields in the northern part of the state; Texas, oil; Utah, coal; West Virginia, coal and oil.

AS NEW MINING DISTRICTS are opened up in Alaska, additions, betterments, and extensions of the Alaskan railroad will be required, according to Colonel Steese, of the Alaskan Engineering Commission. The railroad has a mining department under a consulting geologist of the Bureau of Mines who has a general supervision over mining activities in their relation to railroad operation. The commission has closed the Eska coal mine and abandoned the Chickaloon mine to encourage private investment. The coal reserve of the railroad will be exhausted this year and a small reserve of 10,000 tons is recommended. There has been constructed a four-mile spur connecting newly developed coal mines in Moose Creek, which it is estimated will save the cost of its construction in two years through the lower cost of coal. Mining supplies are carried by river boats operated by the Commission from Nenana to Fort Gibbon and Holy Cross.

The Miner's Torch

Who Furnishes the Inspiration?

IN MY Christmas stocking this year I found a book of Proverbs. I have just been looking at it and out of curiosity turned to the index to see what subject was allotted the most space. Of course, it was money. Here are the first three quotations on that subject:

"A man without money is a bow without an arrow."

"A man without money is like a ship without sails."

"A man without money is like a bird without wings; if he soars he falls to the ground and dies."

One of these quotations is from the Dutch, one from the Roumanian and the third is marked anonymous. All of them could easily have been written by the same author and I have seen at least a score of variations on the same theme in English and American literature.

I hate to question the wisdom of the ages, as it were, but here goes. It is my conviction that the most overrated influence in the world today is that which is credited to money. You men who are living in mining camps, look around a little and see if all of the men and women who are "getting on," as it were, must give the credit for their "soaring" to money.

I did that very thing years ago when I first went to live in mining camps—I mean that I did the looking around, not the soaring—and I discovered that generally the person who was accomplishing the most good in the camp was an old maid or a widow or a married woman without children of her own who was taking an interest in all of the young people of the camp, and unconsciously exerting a wonderful influence on their lives, and doing it mostly on a limited allowance.

Picture to yourself a neatly furnished home with a piano, bookcases filled with books and here and there on the wall an attractive picture. Into this home are welcomed the boys and girls who have no similar attractions in their own homes and almost before they realize it they develop an interest in music, find pleasure in books and pictures, and come to look upon neatly kept homes as the kind that can alone fulfill their ideals. One house such as I have described owned by one lone woman who has a little love for her fellows can have a tremendous influence on the lives of half of the children of a mining village.

Poor cooking and badly furnished homes and dirty children do not necessarily point to underpaid workers, at least not in mining camps. Compare the incomes of the women who inspire the children in any camp with the incomes of the fathers of the children who need and profit by the inspiration, and see if you can still take the proverb seriously.

The good Lord furnished a few women of this character to each settlement, even though the settlement appears God forsaken to the outsider, and that explains largely why all of the children don't turn out to be anarchists and heathens even in the towns where small provision has been made for the comfort and education of the inhabitants. Many a man who has sprung from lowly surroundings should give most of the credit for his achievements to some woman whom he has entirely forgotten.

*Turbine Room of the Power Plant**

This Mine Power Plant Produces Power Cheaply

Tests Show Cost to Be 0.43c. per Kilowatt-Hour Under Full-Load Conditions, 1.9c. on Idle Days—Many Automatic Mechanical and Electrical Features in the Plant—Stokers Feed Crushed Refuse With Washed Slack

BY C. L. MOORMAN

Chief Engineer, Consolidated Coal Co., St. Louis

A MINE-OPERATED power plant near Staunton, Ill., supplying power to three mines of the Consolidated Coal Co. of St. Louis has now been in operation for a little over a year and has convinced the company that a privately owned plant can produce power at low cost. Unusual economy in the production and distribution of electrical energy has been obtained, although the plant is not markedly conspicuous in size when compared with the large public-utility power houses of the country. Nevertheless, it produces power during 8-hour full-load periods at a cost of 0.43c. per kilowatt-hour, which is far below the cost at which power could be purchased. The average cost per kilowatt-hour for a 24-hour period is 0.74c. when the mines are operated at full time and 1.9c. on idle days, these figures being based merely on the direct operating charges.

This company owns and operates, among many others, three mines known as Nos. 7, 14 and 15, located approximately at the three points of an equilateral triangle about three miles on a side, the areas allotted to the various shafts being so large that they meet each other. These mines have a combined daily capacity of 13,000 tons. Each mine has a large coal-washing and screening plant in addition to the customary raw-coal screening facilities all of which require a considerable amount of power for their operation.

With the rapidly increasing use of electrical power

*Steam at 175 lb. pressure and 100 deg. superheat is delivered to these three turbo-generator sets from four water-tube boilers each rated at 600 hp. and fired by automatic stokers. The three generators have a capacity of 3,500 kw. and deliver 2,300-volt 60-cycle three-phase electrical energy which is stepped up to 13,000 volts for transmission.

to drive underground locomotives and coal-cutting machinery and the substitution of motors for steam drives in the operation of preparation machinery, shops, washeries, pumps, etc., it was found that the use of steam-engine driven direct-current generators at each mine was proving not only uneconomical but inadequate.

Early in 1921 work on the construction and equipment of the central power-generating station at Mine No. 15 was undertaken. This plant was designed to furnish necessary electrical power for operation of the three mines under normal conditions with ample power surplus available for any prospective increase in the number or size of motor-driven machines or other facilities.

Appearance and utility were both considered in the design of the building, its equipment and appurtenances. A heavy structural steel framework rests on massive reinforced-concrete foundations. Pressed-brick walls enclose the steel supports and steel-framed windows and doors provide openings. The buildings are 89 ft. wide, 117 ft. long and 49 ft. from floor to roof, the basement under the whole being 15 ft. deep. A tapering white concrete chimney 11 ft. in diameter at the top, 240 ft. high, embellishes and adorns an exterior already pleasing.

Equipment comprises four water-tube boilers each of 600 normal rated horsepower fired by automatic stokers and furnishing steam at 175-lb. pressure and 100-deg. superheat to three turbo-generators which deliver 3,500 kw. of 2,300-volt 60-cycle three-phase electrical energy.

For transmission this energy is stepped up to 13,000 volts and again transformed back to 2,300 volts at the

distant mines. At this voltage it is used to drive motor-generator sets some of which are located above and some below ground. These convert the energy into direct current at 250 volts. To supply power to various above-ground motor drives, several transformer banks are employed which reduce the pressure of the alternating current to 440 volts. The ventilating fans at each of the mines are driven by 2,300-volt alternating-current motors capable of 50-per cent speed reduction.

A recently erected preparation plant at Mine No. 15 is furnished with picking tables where pieces of coal containing impurities are separated from the run-of-mine coal as it is spread out and conveyed into railroad cars for shipment. A portion of these separated lumps having bands of sulphur or slate or pieces of coal with slate or pyrites adhering to them are crushed and conveyed to the boiler room and utilized to make steam instead of being thrown out to waste piles as is the custom at many mines, thus effecting a material reduction in cost of power by use of a fuel which is so low grade as to be without market value. The stokers also

BOILER-ROOM INSTRUMENT BOARD

Here automatic weighing devices record the exact quantity of coal consumed by each boiler, the temperature fluctuations, the flue-gas composition, the pressures of steam, water, draft and vacuum; the steam and water flow and the chemical and mechanical changes in converting latent coal energy into power.

use at times of heavy load No. 5 washed slack and raw screenings together with the refuse.

The power plant is equipped with a complete outfit of measuring and recording instruments, regulatory and control devices. As the fuel passes from overhead coal bunkers into chutes leading to stokers it is automatically weighed and recorded so that the quantity of coal burned under each boiler is determinable at any time. In the turbine room is located a group of indicating and recording instruments, the antennas of which reach out to every part of the plant where the various changes taking place are shown and charted.

Instruments automatically chart pictures of diagrams of temperature fluctuations, flue-gas composition; steam, water, draft and vacuum pressures; also the quantities of steam and water flow, and make graphic records of chemical and mechanical changes that occur in converting coal into heat and electrical energy.

These records assist the engineer in controlling the temperatures of the feed water entering and leaving the heaters and of the cooling water entering and leaving the condensers. They aid him by recording the air temperatures inside and outside the plant, in standardizing the cooling of the air discharge at each generator, and in maintaining below fixed levels the temperature of the oil in bearings and of the exhaust steam leaving each turbine. He is enabled also to regulate the combustion temperatures of the furnace gases in the first and last stages of the boiler.

AUTOMATIC SWITCHBOARD WHICH CONTROLS DISTRIBUTION

From here the operator has control over the distribution of power to all the mines. Each feeder circuit starts from the plant from a full-automatic circuit-breaker switch.

Pressure-record charts show steam pressures in the main header and in two branches, pressure of feed water to boilers and of make-up water to heater, of water ejected by condenser pumps and air pumps, of vacuum obtained in each condenser, of draft in each boiler and in breeching. Quantity charts indicate how much steam is flowing from each boiler, how much is used by the hoisting engine and by the fan engine, how much water is passing to boilers from the heaters and the quantity of make-up water entering the cooling pond. Indicating meters and gages are installed throughout the plant, supplementing the recording instruments.

For control and distribution of electrical power an automatic switchboard is used at the main plant, others being placed at the substations at Mines Nos. 7 and 14. Switches, fuses, circuit breakers, relays and all the intricate and heavy apparatus for controlling the power output are set up in a walled-off corner of the basement of the plant. On the main floor are a series of light slate panels on which are mounted push buttons, switches and instruments which function to control and show the pressure and quantity of current being de-

NEW POWER PLANT SERVING THREE CONSOLIDATED COAL CO. MINES

It was built a year ago at Mine No. 15 in Macoupin County, Ill. The stokers handle practically all of the crushed refuse from the picking tables, burning also washed and raw slack, which is delivered into the boiler-room coal hoppers through the long conveyor shown in the picture.

livered by the generators and also the quantity sent out over the transmission lines.

By means of push buttons on an automatic switch-board the operator closes a circuit to magnetically operated switches in the basement which instantly put power on any desired feeder line. The installation of indicating and recording instruments for the electrical end of the plant also is very complete and in combination with those at the substations permits a correct determination to be made of the output of each generator and of the consumption of electrical energy at each and every point of delivery.

Water for boiler use is obtained from a reservoir about one mile distant, through a 4-in. pipe; a motor-driven centrifugal pump at this pond is started and stopped by throwing a switch at the power plant.

A daily record form is filled out by the operating engineers on which is shown the economy obtained for each twenty-four hour period, this being a résumé of various chart readings and the conclusions based thereon. On this form is recorded how much and what kind of fuel is used and how much water is converted into steam, giving the evaporation of water per pound of fuel; how much steam is used to drive generators and the weight of steam used for each kilowatt-hour of electrical power produced.

Tests show that power is being produced at this plant at an average cost of 0.43c. per kilowatt-hour during the 8-hour hoisting period with full-load conditions. The cost averages 0.74c. for a 24-hour period when the mine works full days and reaches a maximum of 1.9c. during idle days. These figures cover the wages paid to operatives, fuel cost at market price, upkeep, lubricants and all other direct operating charges, but not interest, depreciation, overhead or profit.

Wages of the operating force total about \$2,000 per month, maintenance and repair men's wages are about \$500; lubricants, repair parts, waste and all other material cost about \$1,500; an aggregate monthly cost of \$4,000 for wages and maintenance, averaging \$133.33 per day. Fuel is charged to the plant at an average price of \$1.50 per ton, and the quantity consumed varies from 75 tons on days when none of the mines is working to 131 tons when all three are operating.

About 40 per cent of steam production at the plant is used for hoisting, ventilating, heating, pumps and other auxiliaries connected directly with mining coal at Mine No. 15, the balance going to turbines for generation of current.

Investigate California Coal Deposits

Although coal has been known for a long time to be present upon the Middle Fork of the Eel River, Mendocino County, Calif., no serious efforts have been made to develop the deposit. According to C. McK. Laizure, a thorough investigation of the beds is now under way. A. L. Fisher, of San Francisco, has put a crew of men at work driving a slope on the dip of the bed. The slope is more than 500 ft. long and exposes a coal vein 12 ft. thick. The coal is of the sub-bituminous type and is comparatively low in ash and of excellent quality. Although not conclusively proved it is believed that the inclosing formations are Cretaceous. The Camp Carbon coal mine is at an elevation of 1,800 ft. and six miles from Dos Rios, the nearest railroad point. It is expected that the coal will find important application in the industrial development of California. The property is under option to the Carbon Co., of Oakland, Calif.

Coal Companies Lead in Tree Planting

DURING the spring of 1923, says the *New York Central Lines Magazine*, thirty-eight coal companies set out more forest trees than any other group of tree planters in Pennsylvania. The trees planted aggregated 1,137,175, which is sufficient to reforest 1,200 acres of idle land. As showing the great interest taken in this direction, it is only necessary to state that eight years ago the mining companies planted only 7,600 trees. Of the thirty-eight companies, the Clearfield Bituminous Coal Corporation led with 163,000 trees.

The forestry department of that company was organized in the spring of 1920. The corporation's coal holdings amount to 150,000 acres, of which 24,000 acres are owned in fee and available for reforestation. A survey of this surface proved that 2,000 acres were covered with virgin timber, 16,000 acres with natural reproduction, 4,000 acres barren, 1,000 acres semi-barren near mines, and 1,000 acres of farm land. With this acreage the following forests were established:

Name	Acreage	County
Peale	15,000	Centre and Clearfield....
Bigler	1,700	Clearfield
Patton	4,500	Cambria
Total		21,200

The rest of the acreage is scattered in small tracts near the corporation's mines, notably at Sample Run and Barr Slope, Indiana County, Pa. To the north, east and south are extensive forest lands under state control.

A study of the soil and geographic location of the various tracts, indicated that the best results would obtain by planting white, Norway, Scotch and pitch pine; Norway spruce and European larch, and 431,000 seedlings supplied by the state have been set out since the spring of 1921. Unfortunately, however, the department is unable to furnish more than 50 per cent of annual requirement; and in order to make up the deficiency and to carry out properly the extensive plans contemplated it has become necessary for the corporation to establish its own nursery near the mining town of Clymer, Indiana County, Pa.

Planting seedlings on barren land and watersheds is but a small part of the work accomplished by the corporation's forestry department. In the Peale forest of 15,000 acres particular care is given to natural reproduction and underplanting. Fire lanes have been cut, old roads opened and a fire tower erected and connected with state towers by telephone. In the important work of protection against fire, the forester is receiving the hearty co-operation of the State Forestry Department and the Pennsylvania Fire Protective Associations.

The Peale forest is made up of 2,000 acres of virgin timber, the rest of the area consisting of forest growth in various stages of development. There is also in this forest a large quantity of sound dead timber, that fire killed many years ago. This virgin and dead timber forms the source of the present mill supply. When this is gone the second growth will be ready for the mill, and there is enough of it to supply the mines until the seedlings planted today reach maturity. In cutting the timber the selective method is employed, which is most essential where conservation is the main objective. In three years this forest has produced 3,032,751 board feet of lumber, of which 50 per cent was used for mining purposes and the rest for new construction and repair work. The corporation, with a confidence born of past achievement, may well look forward to the day when its timber supply will largely exceed the demand.

News Of the Industry

Miners Want Four Years' Contract on "Best Terms Obtainable"

Convention Gives Union Negotiators Much Freedom for Coming Wage
Conferences—Lewis Beats Down Rebels—Klansmen
Lose—Howat Thrown Out

By E. W. DAVIDSON

The United Mine Workers are ready. In a two weeks' convention at Indianapolis, Ind., marked by much hullabaloo from a comparatively small radical wing, they built the platform on which they will stand when they meet the bituminous-coal operators in wage-scale sessions opening at Jacksonville, Fla., Feb. 11. The platform calls for a four-year contract under "the best agreement possible to obtain . . . on a basis of no reduction in wages," and gives the union's negotiators more latitude than they have ever had in recent history, requiring only that they submit to the rank and file on referendum whatever agreement they can win from the operators.

The tone of the convention was not militant. When President Lewis and Secretary Green declared the union is weakened and years for a period of peace, they were applauded. Therefore demands for more pay and attacks upon the administration's program for a four-year contract were set upon solidly. The union will fight if necessary, administration spokesmen said, but if it can retain for a term of years the present scale, which is "the best that ever prevailed in the industry," it will be happy to have peace and recuperate for whatever battle may be necessary later.

Committee Has Broad Powers

The scale committee's report, adopted without a change, creates a big policy committee with practically unhampered powers to give to the negotiators. Also, a pertinent clause permits outlying districts to make agreements with their operators before a basic scale is made in the Central Competitive Field, if the chance arises and the union policy committee thinks best.

The convention had the usual outbursts. A small radical element led by such men as John Hindmarsh and John Watt, both of the Springfield district of Illinois, campaigned against the administration on all occasions, great and trivial. But they lost miserably on such radical issues as recognition of Soviet Russia by the United States and alliance of the Mine Workers with one great labor party in this country.

They lost their battle for Myerscough and Howat and on everything strictly radical and were a menace to the Lewis forces only when they allied themselves with the members who think Lewis is too domineering.

On three points during the convention the administration was staggered. It barely saved itself in the battle which preserved the president's right to appoint organizers. The large element which tries biennially to change the constitution so as to permit election of organizers by districts won its point by a standing vote and lost by only 157 in the only roll call of the convention. It was a close shave for the administration.

The second staggering blow was dealt in the Ku Klux Klan battle. The administration tried rather halfheartedly to lift the union ban against Klansmen on the ground that the ban

is unenforceable. The anti-Klan forces, however, beat down the proposal. This issue was called "the most delicate of the convention."

The third was the fight to get more delegates into the convention from the big locals such as those in Illinois. The rebels led this fight and fell but 12 votes short of getting a roll call on it. They charged a miscount and yelled for 45 minutes or until the adjournment that day.

Convention Has "Atmosphere"

All the way through the two weeks of deliberation in old Tomlinson Hall the rebels continuously rebelled, President Lewis continuously defied them with such famous phrases as "You may meet in Hell before I'll change the rule," the 1,900 delegates all continuously strove to make at least one speech to be reported back home, and the heavy odors of fried onions and hot dogs from the hallways and of stale fruit from the great market downstairs continuously filled the place. For once the voices of speakers from the rostrum reached every corner of the hall, thanks to a "magnavox" installed by the telephone company, and it must be said that white mule was conspicuous for its absence. In every other particular the convention was conventional.

An effort to change the constitution

What the Miners Want

The report of the Scale Committee adopted by the miners convention unchanged, follows:

"(1) We recommend to the convention, in lieu of all resolutions relating to wages and working conditions that have been presented, that the properly accredited representatives of the organization be authorized and instructed to secure the best agreement obtainable from the operators in the Central Competitive Field on the basis of no reduction in wages and that any agreement so secured be submitted to a referendum vote of the membership for ratification.

"(2) We recommend that the next wage scale cover a period of four years, beginning April 1, 1924, and ending March 31, 1928.

Policy

"(1) For the purpose of meeting in a practical and constructive way all unforeseen emergencies which may arise a Policy Committee composed of the Scale Committee of

the Central Competitive Field, three representatives from each outlying district, the members of the International Executive Board and the International officers, be authorized to take such action for the protection of our best interests as circumstances may require and to advise the membership on unexpected developments which may arise and which cannot now be foreseen.

"(2) The committee recommends that the outlying districts be authorized to enter into wage-scale negotiations with their respective operators when the opportunity presents itself, it being understood, however, that no outlying district will conclude an agreement until after an agreement for the Central Competitive Field has been secured, or permission to do so has been granted by the policy committee.

"(3) The committee recommends that all contracts in the bituminous district run concurrently and expire on the same date."

to strip President Lewis of the power to arbitrarily remove district officers and appoint others was reported unfavorably by the constitutional committee and was beaten by vote.

An effort to get the constitution changed to make all agreements national instead of determined from a basic agreement made in the Central Competitive Field was killed.

The big fight to strip President Lewis of the power to appoint organizers started Tuesday forenoon. Some feel Lewis uses organizers to maintain "his machine." Secretary Bittner of the committee, defending a negative report on the matter, denied there are "hundreds" of such men on the payroll and that organizers work for the "machine." He said union-fighting operators would be pleased to see organizers elected by the rank and file.

Lewis made little attempt to defend himself, evidently thinking it better generalship merely to tell the convention he was willing to leave the matter to the delegates. It appeared to be a disappointment to the Lewis faction, however, when the debate was brought to an abrupt end by John Watt, of Springfield, Ill. Watt got recognition on the floor, and then, proceeding to the platform as if to make a speech, merely moved that debate cease. The motion was seconded by a roar from the rebels, and the committee's report went to a vote. The rebels won, 760 to 734, but the administration obtained a roll call by a standing vote of 689.

Lewis Has Close Call

The Lewis administration won the roll call, 2,263 to 2,106, or by a narrow margin of 157. The States of Indiana and Illinois, the Canadian delegation and scattering sections in Pennsylvania and elsewhere voted against Lewis. It was noticeable, however, that Frank Farrington, president of the Illinois miners, who until last year was a bitter opponent of Lewis, voted for the administration. Wednesday afternoon a delegate rose to protest the roll call, saying he could prove that illegal votes had been cast for the administration. President Lewis sternly declined to recognize him.

During Wednesday afternoon the administration defeated a long list of resolutions aimed to shear the headquarters officers of many powers. A resolution requiring merely a majority vote of the executive board to call a general strike was defeated. A two-thirds vote of the board is now required.

Almost a riot ensued when the committee reported against a resolution changing the basis of representation in the convention. The resolution would have changed back to the old plan of allowing a delegate in the convention for every 100 members of each local. The present arrangement, put through with a fight at the last convention of 1922, permits only one delegate for every 500 members in the big locals but one for each local smaller than that. This was aimed at such regions as recalcitrant Illinois, where many locals are big. The present plan has a decided effect on aye-and-no voting, because it reduces the number of delegates, but of course it has no effect on roll calls, for one vote always is cast

Main Acts of Convention In Its Final Week

Adopted scale committee's report unchanged, calling for four-year agreement with operators on best terms obtainable.

Refused to remove constitutional membership bar against Klansmen.

Preserved president's power to appoint organizers after bitter fight. Administration won, 2,263 to 2,106, in only roll call of the convention.

Defeated many other resolutions to shear Lewis of power.

Refused to reinstate Howat and Myerscough.

Rebels failed by only 12 votes to get roll call on resolution permitting more delegates from big locals such as those in Illinois. Near riot followed.

Elected Van A. Bittner and Thomas Kennedy delegates to International Mining Congress in Prague next June.

Chose Indianapolis over St. Louis for 1926 convention.

for every 100 members in each local, no matter what the size of the convention.

The standing vote on this question supported the administration, 785 to 692. Of course a howl arose. On a motion for a roll call the count was 558. Since this lacked but 12 of enough to get a roll call, the convention fell into a roar of protest against the tellers' count in spite of President Lewis' best efforts. Alex Piazza, of District 5, was knocked down by somebody unknown.

Rebels Howl for an Hour

Every time Lewis recognized chairman Van Bittner, of the constitution committee, so that the committee report could proceed, the rebels howled. For nearly an hour this thing kept up. Then Lewis got silence just long enough to declare: "You may shout until you meet each other in hell and you won't change the rule of this convention!"

Although the dangerous resolution to permit Ku Klux Klan members to be United Mine Workers was just ahead and might easily have been railroaded through during the hubbub, this was not done. A few innocuous sections of the committee's report were adopted amid the noise and at 5 o'clock the gavel closed the day's doings. There followed much rebel talk in the halls about a demand for the election of tellers from the house instead of continuing with the Lewis appointees.

Thursday morning Secretary of Labor James J. Davis made the address reported in another column, advocating a settlement running for a term of years, urging the miners' union to maintain a research bureau to gather statistics on coal from the labor standpoint, favoring selective immigration to protect miners and other American labor from a flood of cheap foreign workers, and answering hotly the jeers of the rebel element in the convention who booed him when he began.

In the afternoon the main business of the convention—the scale report—came up, with the resulting acceptance of the most important section, which empowers the miners' scale committee to get "the best agreement obtainable" from the operators, instead of filling up the platform with demands for more pay and shorter hours.

Frank Farrington, chairman of the committee, prefaced his reading of the report by saying he knew it would not appeal to those of "extreme and impossible views" but that it was the best thing that could be adopted for the benefit of the whole union organization in all its ramifications.

The report, giving the miners' representatives free power to obtain the best agreement possible, recommending a four-year contract running concurrently in all districts, creating a miners' policy committee and authorizing outlying districts to start negotiations "when opportunity presents itself" and make agreements either after the Central Field agreement has been made or before with the permission of the policy committee, was greeted at once by the attack of the six-hour-day and five-day-week element.

Illinois Leads Attack

About all of the attack came from Illinois, Farrington's own district, which is now largely out of his control. Delegate Hindmarsh made a long speech for shorter hours, declaring the miners' union is moving backward instead of forward by not demanding the six-hour day and five-day week. He had a great deal to say about the 7-hour day in England. William Roy, of Ohio, asked him if American miners would like to have a 7-hour day under the low wages and hard conditions of the Britons. William Mitch, of Indiana, said the British miners have lost heavily in the past four years and that wages in some of the 13 districts of England are lower than the cost of living.

"The boys back home in this country," said Mitch, "would rather strike to prevent a reduction in wages, if a strike were forced upon them, than to strike for a shorter working day." A section of the convention yelled "No!"

The broken condition of the British miners was pictured by Vice-President Philip Murray, who said they had taken three reductions and got only one small increase, along with their 7-hour day, in the past four years. He quoted Frank Hodges, secretary of the British miners, to the effect that the Britons should at once adopt the militant policy of the American miners.

"Four years of peace will enable the United Mine Workers, as the only constructive force in the coal industry, to put forth a program that will save its membership," said Murray after he had spoken of the "chaotic and diseased" condition of the industry because of overdevelopment and overmanning.

"If we struck, what would be the cost? Every strike has brought thousands of men into the industry and it would do it this time. In 1922, when the men of the coke field struck with the rest of the country, they mostly went elsewhere to work and new thou-

sands are now in there taking their places."

He said the 6-hour day proposal would only be trading ground at best, for non-unionism is a menace that makes the short day an utter impossibility.

Frank Farrington, once a power behind the move for the 6-hour day but now lined up with Lewis against it, admitted it would be suicidal to unionism. He granted that about eight years ago he was one of the pioneers for it and sent out a circular to his members favoring it. But it is pure theory nowadays, he argued, and is fit only to be used "for grandstanding."

"West Virginia," he said, "is now able to produce 100,000,000 tons of coal, or one-fifth of the whole normal need of the country. There are enough non-union men in the land to produce all of the coal the country needs. The situation down in that West Virginia region is so severe that you have heard a man from there say he doubted if any agreement could be made with operators that did not cut wages."

Then Farrington touched upon the weakness of the union. When the 1922 strike started, he said, Districts 29 and 17, both in West Virginia, were 100 per cent strong. Now, he doubts if there is a single due-paying member of 29 left, and 17 has lost about 14,000 men. In such a field the 6-hour day would make it impossible for the union regions to sell any coal at all in competition with the non-union mines.

"There are other things to be said against the 6-hour day," finished Farrington, "but it is not advisable to say them because they would only become arguments in the mouths of the common enemy, the operators."

Lee Hall, president of the Ohio district, whose bailiwick voted in its state convention for shorter hours and 25 per cent more pay, declared he favored a shorter day, but there are times when such a demand cannot be made. Other benefits for the union miners in various districts are more to be desired.

Union Weary of Strikes

"We're weary now, after having suffered from the five months' strike of 1922," said International Secretary William Green. "Let us fight only when we want to. We don't want to now, even though there are a lot of non-union operators who would like to have us do it. Let us have a spell of peace. When the time comes and the necessity confronts us, then we can do our fighting."

A West Virginia delegate declared he thought there certainly would have to be a fight if a reasonable agreement were to be made for West Virginia. He feared a reduction in wages. President Lewis answered that the scale for West Virginia would be the scale for the whole Central Field. The union spent a million dollars protecting its frontier there in 1922 and would continue to protect it.

The defenders of the 6-hour day from Illinois pointed to the advancement of machinery in mining, which is helping the "big fellow" among the mines to swallow up the little mining businesses, thus throwing more men out of jobs. It was argued that the shorter work-

John Lewis' Keynote

Looking forward to April 1, President Lewis said this to the miners' convention: "In every moral and economic way the country and the mine workers would profit by a settlement for a term of years at a wage scale which, at the very worst, would be the best that ever prevailed in this industry. I know my people will fight if necessity arises, but I would be a false leader indeed to lead them into battle unnecessarily. I know that the mass of my people desire peace. Securing a four-year contract would be one of the greatest accomplishments in the history of this organization."

day is the only defence against this movement that can be raised so long as mines remain in private ownership.

A number of questions were asked. Ohio delegates were assured they could, under the proposed plan of settlement, go home after the basic scale was fixed, and make the best deals they can with their district operators to get a scale for the removal of roof slate, which now has to be loaded out free.

"In case there is a strike," asked another, "will there be a referendum to the members before any settlement is signed?" Farrington said that would lie with the policy committee. This was hooted by the rebels.

Finally the case had been set up so strongly by the administration that the first section of the report was adopted readily by a show of hands and the convention adjourned for the day, leaving the balance of the report to be acted upon later.

On Friday morning the balance of the scale committee's report was adopted without change and without a roll call. However, it gave another opportunity for vocal attack by the rebel element mainly on the ground that four years is so long a period that too many things may happen in that time.

"We could get away with anything during the war in Illinois without getting docked; now we can't get away with anything," complained Thomas Parry, of Divernon, Ill., opposing the four-year plan because it would perpetrate "obnoxious" conditions now in

effect in that state. "Why, we can't even load out a piece of impurity the size of my fist," he declared. Vice-President Harry Fishwick, of the Illinois district, tried to get the Parry remarks expunged from the record as not representing the opinion of the organization.

Martin Flyzik, of Washington, defending the report, pointed out that the outlying districts have lost ground in point of wages and need four years to recover. The whole union needs exactly the same thing. After the four years, then it should be ready to fight again. He has seen wages forced down in the outlying fields such as his own where a reduction to \$6.25 was accepted last spring after a long and unsuccessful strike, and he wanted protection for four years against any further reductions.

A peace speech by President Lewis wound up the debate. He pointed out that it took eight months of effort, beginning in December, 1921, to get the settlement that finally ended the 1922 strike in August, 1922, and that after another long effort, a settlement was made to continue the agreement until April, 1924; but in neither case were the miners able to get a long-term agreement. The industry knew not what was going to happen after a period of but a few months and therefore there could be no stability.

Lewis Makes Peace Speech

"It is obvious," said Lewis, "that in every moral and economic way the country and the mine workers would profit now by a settlement for a term of years at a wage scale which at the very worst would be the best that ever prevailed in this industry. I know my people will fight if the necessity arises, but I would be a false leader indeed to lead them into battle unnecessarily. We suffered some inconvenience in the strike of 1922 and many a man has not yet got out of the debt incurred then. I know that the mass of our people desire peace. Securing a four-year contract to begin April 1, 1924, would be one of the greatest accomplishments in the history of this organization."

"Someone gets up here and fears that another war might occur during the period of a four-year agreement and that the contract would not permit the loading out of impurities then. God forbid such reasoning will prevail in the consideration of matters of such consequence as this. In 1917, although we had a contract, your representatives in a logical presentation of the case to the operators, were able to open that contract to meet the conditions prevailing. In another war the coal industry would meet the situation in just as intelligent a way."

"Arguments for a four-year contract at no reduction in wages are such that it is not advisable to voice them here when my words are to be carried far and wide. Those reasons ought to be obvious to all well-informed United Mine Workers. When 29 district presidents unanimously favor this report it should be accepted."

An anthracite delegate asked whether the next anthracite agreement would be made to run concurrently with the

Illinois Operators Against 4-Year Plan

No important operator in Illinois favors the four-year agreement which the miners are asking. They regard the four-year plank as union trading ground. A considerable number, however, talk favorably of a two-year continuance of present wages, though there are more who are willing to grant only one year. A considerable group demand a wage cut. The Illinois delegation goes to Jacksonville uninstructed and will take its position after it has "talked with our Eastern neighbors."

bituminous agreement. Lewis replied that since the situations regarding the two kinds of coal are so different—less than 16 per cent of soft coal going into domestic use while more than 60 per cent of hard coal does—the officers are unable now to make a ruling on the question. The decision would be determined by conditions as they arise. Someone wanted to bar anthracite delegates from any forthcoming referendum vote on a bituminous scale. This was squelched. Then the scale committee report went through.

A victory for the anti-Klan men ended a two-hour battle to change the constitution so as to remove the clause barring proven Klansmen from the United Mine Workers. This, according to Secretary Van Bittner, of the constitution committee, and other speakers, was "the most delicate question before the convention." In all the bitter debate that followed, not one speaker frankly defended the Ku Klux Klan though there were many shouts and much muttering from all parts of the floor.

The convention elected Thomas Kennedy, of Pennsylvania, and Walter Nesbit, of Illinois, delegates of the United Mine Workers to the International Mining Congress in Prague next June. No other candidates ran close to these, although John Hindmarsh, Frank Ledvinska, Fred Mooney and Andrew McGarry were runners up.

Alexander Howat Squelched

A decisive blow at radical strength in the union was delivered by the administration on Saturday, Feb. 2, when the convention wound up in a blaze of excitement. The drives to get Alexander Howat, of Kansas, and Thomas Myerscough, of Nova Scotia, back into the union crumpled against the stone battlements of Lewis' strength. The appeals and grievances committee, after agreeing earlier in the convention to reconsider the cases of the two rebel leaders, ousted for defiance to headquarters, finally reported against them Saturday morning. President Lewis refused Myerscough permission to speak. Then the convention upheld the committee by a show of hands.

Howat, determined not to be sat upon so firmly, waded up an aisle toward the platform, demanding a chance to talk. Amid wild disorder, sergeants-at-arms grabbed the man and dragged him out of the hall. The roar of the rebels was threatening, but Lewis warned the convention that "any attempt to rush the stage or to force the chairman to do otherwise than refuse Howat a voice under the law of the organization, would fail." This warning, backed up by the massing of loyal Lewis men, stopped an abortive rush and left the convention in loud confusion which lasted until Lewis whacked the gavel block, ending the 29th consecutive and sixth biennial convention of the United Mine Workers.

Howat, who is not even a Mine Worker and of course not a delegate, then went outside and held a rump convention. There he made his speech.

The 1926 convention of the union will be held in Indianapolis, as the last two have been. St. Louis was voted down.

Secretary Davis Faces Down Miner Rebels

Urges Long-Term Contract Without Wage Cuts—Wants Miners to Have Research Bureau and Joint Interpreters of Contracts

Facing the booing of a small radical element in the miners' union convention at Indianapolis, Jan. 30, James J. Davis, Secretary of Labor, went out from Washington advocating several things. He urged the union to create a bureau of research to gather data on coal from the labor standpoint, to secure for the industry joint interpreters of contract in each region; he declared for a long-term wage contract without wage reduction to give the coal industry a chance to "recover"; he argued for the passage of a new check on immigration before next July 1, when the 3-per cent immigration law goes off the

Secretary Davis' speech, in which he waved one of the radical handbills and declared he was always ready to face any issue so long as the opposition would listen to facts.

After his speech of one hour and twenty minutes, Lee Hall, district president from Ohio, proposed a resolution condemning the anti-Davis handbill as "a slanderous, untrue, un-American, dirty sheet," promulgated by men "without honor or principle and too cowardly to sign their own names." The resolution passed with four rising to vote against it.

Secretary Davis, in advocating a new immigration law to stop a flood of aliens ready to burst upon this country July 1, when the present law expires, said it is possible for more than a million a year to come and that they would create chaos here, working for little and displacing American labor. Had it not been for the 3-per cent immigration law now about to run out, he declared, between three and five million more men than are now out of employment would be jobless, with consequent disorder all over this land.

"Do you need more miners," he asked, "when you've already got 244,000 more than the industry can give five and a half day's work to?"

"No!" shouted back the convention.

He revealed that even under the 3-per cent law, foreign labor is stealthily sneaking into the United States in large numbers. "Bootlegging" of foreigners goes on all the time, netting the "bootleggers" from \$250 to \$2,500 a head for every alien brought in against the law. Asiatics come in through Canada and Mexico, he said, and about 30,000 a year get here by violating the seaman's act. Mexicans, he said, are brought in by trainloads, especially during periods of strike or impending strike, as in the case of Colorado and Utah coal mines.

He denied the accusation in the rebel handbill that he favored the Rosenbloom and Kelly bills now before Congress, saying he has a better one himself, and denied also that his plan for alien enrollment in this country would result in deportation of every alien who might strike. He defended the enrollment plan, saying it would enable this country to reach all its aliens to instruct them in their rights and duties as Americans and would be a thing of value to them rather than a detriment. We enroll all Americans for voting and enroll all Americans for schooling, so why should Americans protest against enrollment of aliens within our borders?

He denied the charge that he favors cutting of wages, saying if wages were reduced \$1 a day for the 41,000,000 gainfully employed workers in this country, the reduction of \$41,000,000 a day in the nation's buying power would be disastrous to industry.

Secretary Davis declared for government rehabilitation of injured workmen to reduce pauperism and de-

James J. Davis

Some of the mine workers' delegates did not want to hear the Secretary of Labor and tried to hoot him down, but wiser counsel ultimately prevailed.

statute books, and favored not only selective immigration from transoceanic and adjoining nations but also enrollment in this country of all aliens.

Secretary Davis was greeted in Indianapolis by a convention full of posters and fliers denouncing him as an enemy of labor and one who would like to see miners' wages reduced: The rebel plan in the meeting evidently was to hoot him down. Realizing this, President Lewis in the chair, declaring Secretary Davis to have been "always square to the United Mine Workers of America," asked for Mr. Davis "that privilege which you would grant any honorable man." This merely drew a chorus of "Boos!"

"The honor of your organization is at stake," roared Lewis. "You are standing before the entire nation and this organization is going to be judged by the acts of this convention. If there are any men here so devoid of the natural instincts of a gentleman that they cannot accord the courtesies due the Secretary of Labor, let them leave the hall at once." Of course nobody left. Instead they merely "moored" occasionally during the beginning of

pendency in this country. An average of \$400 will add an average of 20 years of independent useful life to such men, he said. "Isn't that a better way to get labor than to import it?" he queried. Two mine explosions killing nearly 100 men within a week reminded him of the necessity also of more effort to make the coal mines of this country safe.

Advocating research bureaus among labor unions he said:

"Your organization has now reached the stage where you should create your own permanent research bureaus, which would furnish your own and joint conference assemblies with specific and reliable details of the local variations in your cost of living as compared with the city centers furnished by the Department of Labor—also the coal markets, their sources of supply, the way and wherefore of the variations in freight rates, costs of production, selling prices both wholesale and retail, profits and evidences of profiteering, if any, and by whom.

"Such research work covering a period of coal shortage would quickly expose the spot-coal gamblers, who are the worst menace of the industry and therefore its worst enemies because their piratic activities besmirch the reputation of the industry and create the unwarranted impression that the coal business is a 'hold-up' game of conspiracy between employers and employees.

Would Eliminate Spot Gamblers

"Continued harmony in the industry for, say, 5 years would eliminate for the time being all the spot or short coal gamblers and pave the way for the solution of most of your troubles.

"I congratulate you on the way you resolved last Saturday to handle another disturbing factor in the coal industry and which can be remedied only by the co-operation of your officials and members. It is that of the sporadic local strike. Scores of these petty affairs occur every year, and as a direct result public confidence is shaken in the integrity of joint contracts.

"Now I know from personal experience in dozens of cases that come to the Conciliation Service of the Department of Labor that your leaders generally disapprove and do all they can to prevent these illegal petty strikes in violation of your agreement; yet some of the rank and file in too many instances proceed without the sanction of their district and national officials.

"Of course I understand that these petty strikes are intended as protests and to convey the idea of lack of local confidence that they are getting a square deal; but they should understand that neither the interpretation of the contract nor the decision of any local dispute rests with the local union, and the failure of so many local unions to appreciate this, by taking matters into their own hands, brings down upon the whole organization official and public censure.

"Now it strikes us that there is a simple way to correct this evil by the appointment of a joint interpreter of the agreement in each mining district and sub-district, this interpreter to have the sole power to interpret the application of the terms of the agreement

Edgar W. Tait

President, Allegheny River Mining Co., recently elected member of Board of Directors, Central Pennsylvania Coal Producers' Association and of the Executive Committee of the Association of Bituminous Coal Operators of Central Pennsylvania.

to any local dispute—in other words, have the final decision when all the other machinery for adjustment has failed. Understand that this interpreter does not make nor change any part or verbiage of any joint agreement; he merely decides what it means in relation to any dispute, and the virtue of his services lies in its promptness which begets the confidence of all employed.

"The idea of such an interpreter was developed during the war period, and has been continued partly in the copper and oil industries of the Rocky Mountain and Pacific Coast States, with the result that not a single shift has been lost in either industry for six years over any local dispute once the agreement has been made, and I am glad to note that District 17, in West Virginia, is working under the same idea with similar flattering results. Why not expand the idea and clean out the cobwebs of petty strikes that put your organization in such bad light in the minds of so many people?

"The way to hold the confidence of the American people is to keep your contract. Yes, make it the most sacred instrument of your organization.

"Let me again emphasize the fact that the chief needs of the coal industry are: (1) Peace for a term of years, and you will (2) eliminate the spot coal gambler; (3) create your own permanent Research Bureau; (4) appoint interpreters of your local agreements, and (5) you will remove the cause for any petty local strike.

"Thus demonstrating to the country at large that the problems of the coal industry can best be solved jointly by your employers and yourselves."

At the wind-up of his reply to the radical attack on him in the convention by men "more loyal to other flags than to that of this nation" Secretary Davis called Lewis the "greatest president the United Mine Workers ever had" and shook hands with him on the stage. Then the Hall resolution condemning the handbill passed with a whoop.

Two Big Strip Pits Developed In Ohio and Montana

What is considered the biggest slack coal deal in the history of the State of Ohio, involving between 1,100,000 and 1,500,000 tons and approximately \$2,250,000, was closed Jan. 17 with the signing of a contract by the Blanchard Zanesville Mining Co. and the Ohio Power Co. The coal is to be shipped from the Big Muskingum stripping mine of the coal company at Ellis, Ohio, six miles north of Zanesville, to the new plant of the power company at Philo, Ohio, ten miles south of Zanesville.

The contract covers a period of ten years, and the coal is to be shipped at the rate of 300 to 450 tons daily. Extensive improvements at the Big Muskingum mine have been begun in preparation for handling the big output which the shipment of 300 tons of slack daily will entail. Improved types of tippie equipment, including a long picking table and cleaning plant and shaker screens, are to be installed.

This mine came into production in August, 1923, the present maximum output being 1,000 tons daily. New producing units will be installed as soon as practicable and this production will be doubled and eventually tripled. As shipments to Philo may be made by rail or water the loading plant will include a four-track railroad tippie and river tippie. Owing to the great saving in freight it is intended to ship practically all of this coal by river.

The Northern Pacific R.R. has a 600-acre tract of sub-bituminous coal, which is an extension of the Sheridan-Wyoming field located 35 miles south of Forsythe, Mont. This company is in a position to open up seven other similar tracts if it so desires. The coal is 30 ft. thick and will yield from the tract mentioned as much as 26,000,000 tons, the mining of which will require the removing of only 45,000,000 tons of cover. It proposes to strip at the rate of 1,000,000 tons of coal per year for railroad fuel.

Brydon Asks to Be Heard on Stream-Pollution Bills

When the Rivers and Harbors Committee of the House of Representatives met Jan. 30 to consider bills relating to pollution of coastal and navigable waters and inland streams by oil and acidulous materials, Harry L. Gandy, executive secretary of the National Coal Association, appeared as the representative of John C. Brydon, president of the association, and presented a statement by Mr. Brydon on the bills. Six bills were before the committee, two of which, the Bland bill and the Rosenbloom bill, have a direct bearing on the bituminous coal industry.

Mr. Brydon's statement, after reciting at considerable length the effect on the coal industry of the enactment of these measures, asked that the industry, through the National Coal Association, be given an opportunity to be heard through witnesses and briefs in the event that serious consideration be given the Bland and Rosenbloom bills.

Drop Gouge Charge Against Madeira-Hill Co.

The Federal Trade Commission has dismissed the case against the Madeira-Hill Co. involving charges of conspiracy to increase the prices of certain sizes of anthracite through pyramiding, according to an announcement by the commission Feb. 2.

The commission said no evidence was adduced showing the Madeira-Hill corporation had an agreement with wholesale customers to sell anthracite at stated prices. The wholesalers mentioned by the commission included Pattison & Browns, Inc., the Titan Fuel Corporation, Hartwell-Lester, Inc., C. P. Brodhead and Lynn M. Ranger.

The original action was instituted on request of the President to consider findings of fact of the U. S. Coal Commission, together with assertions by Governor Pinchot of Pennsylvania, that the passing of anthracite through numerous hands before it reached the consumer was a device by which the price was unduly raised.

The commission immediately went over the whole situation with the Coal Commission, and then instituted its own investigation, using statistics gathered by the Coal Commission in arriving at its final decision.

"For the purpose of expediting the disposition of this complaint," a formal statement by the Trade Commission said, "the commission adopted the hitherto unusual procedure of itself hearing, under oath, the testimony of the witnesses adduced by the commission's attorneys in support of the complaint and of the respondents' denial.

"It very quickly appeared that the general statements made in the report of the United States Coal Commission were not applicable to Madeira-Hill & Co., and that the charge in the complaint that Madeira-Hill (the respondent operator) has assured the Pennsylvania Fair Practices Committee that it would sell the grades of coal in question at \$10.50 per ton, f.o.b. mine, and had in fact sold such coal at a higher price, was not substantiated by proof.

"The chairman of the Fair Practices Committee was called and denied absolutely that there had been any agreement between Madeira-Hill and his committee as to the price at which the company was to sell his coal. He stated unequivocally that Madeira-Hill had appeared before his committee, produced their costs of production and requested that the sum of \$11.50 per ton be fixed at which they should sell the sizes of anthracite referred to; that his committee fixed \$10.50 and that Madeira-Hill did not, at any time, agree with or assure his committee that it would sell said coal at the price so fixed.

"Of course, any declarations which might be made by Madeira-Hill, as to the existence of an agreement or arrangement with the wholesaler respondents, could be binding only as to the party making the statement.

"Not only were there no corroborative statements from the wholesalers, with the possible exception of Ranger, but their denial of such arrangement was complete and explicit. In

oral testimony, Ranger himself strenuously denied the existence of such an arrangement and insisted that the arrangement in accordance with which he says in one of his letters he paid an additional \$2.50 per ton to Madeira-Hill, was the arrangement created by the original order and accepted and did not refer to any agreement for a division of profit."

Saunders Named President of United Engineering Society

William L. Saunders, chairman of the Naval Consulting Board and deputy chairman of the Federal Reserve Bank of New York, has, it is announced, been elected president of the United Engineering Society, succeeding J. Viopond Davies. Mr. Saunders is chairman of the Board of the Ingersoll-Rand Co. and a director of other large corporations.

He was twice mayor of Plainfield, N. J., and is a past president of the American Institute of Mining and Metallurgical Engineers, New York Chamber of Commerce, and Manufacturers Export Association. He also is a member of the American Society of Civil Engineers, American Society of Mechanical Engineers and the Iron and Steel Institute.

The report of the retiring president showed that the total membership of the four founder societies which compose the United Engineering Society and which embrace the civil, mining, mechanical, and electrical engineering groups is 54,224. Membership of the associate societies aggregates 25,615.

George H. Pegram, chief engineer of the Interborough Rapid Transit Co., was chosen first vice-president, and J. V. W. Reynders, vice-president of the American Institute of Mining and Metallurgical Engineers, was named second vice-president. Other officers elected are: Alfred D. Flinn, secretary; Joseph Struthers, treasurer; Henry A. Lardner, assistant treasurer.

Byproduct Coke Output in 1923 Made New Record

A new record in the output of byproduct coke was established in 1923, according to the U. S. Geological Survey, which reports that the total production of all coke during the year has been exceeded but twice in the history of the country. The 2,999,000 tons reported by producers for December brought the year's output of byproduct coke up to 37,527,000 net tons. This was an increase of 6,693,000 tons over the 1920 output, hitherto the maximum. The combined production of beehive and byproduct coke was about 55,487,000 tons, an amount almost equal to that of 1917 and only 1.8 per cent less than the record set in the war year 1918.

Production from byproduct ovens passed the production of beehive ovens in November, 1918, and since that date byproduct coke has been continuously in the lead. In 1923, 67.6 per cent of the total was contributed by byproduct ovens and 32.4 per cent by beehive ovens.

OUTPUT OF BEEHIVE AND BYPRODUCT COKE IN THE UNITED STATES

Year	Net Tons Produced			Per cent of Total Output	
	Beehive	By-product	Total	Beehive	By-product
1913	33,584,830	12,714,700	46,299,530	72.5	27.5
1915	27,508,255	14,072,895	41,581,150	66.2	33.8
1917	33,167,548	22,439,280	55,606,828	59.6	40.4
1918	30,480,792	25,997,580	56,478,372	54.0	46.0
1919	19,042,936	25,137,621	44,180,557	43.1	56.9
1920	20,511,092	30,833,951	51,345,043	40.0	60.0
1921	5,538,042	19,749,580	25,287,622	21.9	78.1
1922	8,573,467	28,550,545	37,124,012	23.1	76.9
1923	17,960,000	37,527,000	55,487,000	32.4	67.6

The recovery in coke production was associated with great activity in the iron industry and with a shortage of household fuel.

In comparison with 1922, both branches of the industry reported a great increase in output. For byproduct coke the increase amounted to 8,976,000 tons, or 31 per cent. Production of beehive coke showed a still larger increase because the strike in the Connellsville region had artificially restricted operations the year before.

PRODUCTION OF BYPRODUCT COKE, BY STATES, IN 1922 AND 1923

State	(In thousands of net tons)		Increase (+) or Decrease (—)	
	1922(a)	1923(b)	Tons	Per Cent
Alabama.....	3,493	4,335	+842	+24

Total.....	28,551	37,527	+8,976	+31

(a) Final figures. (b) From monthly reports furnished by operators.

PRODUCTION OF BEEHIVE COKE, BY GROUPS OF STATES, IN 1922 AND 1923

	(In thousands of Net Tons)		Increase 1923	
	1922a	1923b	Tons	Per Cent
Pennsylvania & Ohio	6,939	14,484	7,545	109
West Virginia.....	418	1,037	619	148
Ala., Ky., Tenn., & Ga.....	432	1,079	647	150
Virginia.....	379	721	342	90
Colorado & New Mexico.....	207	371	164	79
Washington & Utah.....	198	268	70	35
	8,573	17,960	9,387	109

(a) Final figures. (b) Estimated from railroad shipments.

The only new plant to start operation in 1923 was that of the Weirton Steel Co. with 37 ovens, which began producing in July. On Jan. 1, 1924, there were approximately 709 ovens under construction, of which 541 were additions to existing plants and 168 were at 7 small new plants.

At 100 per cent operation with all ovens active and all conditions favorable, the plants in existence at the end of 1923 could produce 44,092,000 tons of coke a year. When the ovens under construction are in operation this total will be increased to 48,350,000 tons of coke. The plants now built have a coal-carbonizing capacity at 100 per cent operation of 63,000,000 tons, and this will be increased by the ovens under construction to 69,000,000 tons.

Regulationists Gain Strength from Teapot Dome Developments

Deals Blow to Administration Effectiveness Obtained by Giving Broad Power to Single Officials—Position of Trade Commission Stronger—Pinchot Gains Prestige

By PAUL WOOTON

Washington Correspondent of *Coal Age*

Teapot Dome developments put great strength behind the regulationists. The present administration has placed great emphasis upon less government in business. The development of that policy has meant the placing in private hands of many undertakings which might have been handled as a part of the government's work. It now is certain that no further leases will be made of naval reserves. If it becomes necessary for the government to draw upon them, the federal government will have to go into the oil production business.

One of the indirect effects of the explosion which has blown the lid from the teapot is that it paves the way for the hoisting of regulation on coal and other basic commodities. The part played by the oil magnates not only brings into disrepute all big business but also all of the industries where large aggregates of capital are required for their development. The argument now will be brought forward that the federal government cannot co-operate closely with big business on the ground that the friendly contacts which such a policy engenders means that these interests are favored unduly. It is certain to affect to a great degree all of the leasing being done under the recently enacted General Leasing Act.

The sensational developments in connection with the Sinclair and Doheny leases is a blow to the increased effectiveness of administration which has been obtained of late by giving broad powers to single officials. The trend again will be toward the creation of boards and commissions, where the division of responsibility among several persons is a guarantee against the corruption of a single official.

There is no question that the Teapot Dome matter has strengthened the position of the Federal Trade Commission and is reacting unfavorably on the policies of Secretary Hoover in placing great faith in the integrity of the men conducting our industries.

The developments constitute a great victory for the ultra-conservationists. It has increased Governor Pinchot's

prestige and has placed new pressure behind his coal bill. The interjection of long debates on Teapot Dome will divert attention from coal legislation in the immediate future. The attention of Congress now is centered on the personal ethics of high administrative officers. The tendency still is to dwell on satchels of currency, cancelled checks and the more spectacular features of the incident. It is not going to be long, however, before attempts will be directed at things more fundamental and with them will come, it is believed generally, a wave of regulation which will be applied first to underground resources.

Pittsburgh Coal Co. Takes Over Reiss Interests

Public announcement is made of the affiliation of the Milwaukee-Western Fuel Co., the C. Reiss Coal Co., of Sheboygan, Wis., and the Pittsburgh Coal Co., which really was brought about several months ago when the Pittsburgh Coal Co. bought the interest of the late Edward A. Uhrig in the first-named company. The combine, which practically controls the Lake Michigan trade, shipped 7,000,000 tons by lake last season. V. H. Palmer, of Cleveland, Ohio, will direct all future lake shipments. The three companies will be continued as separate organizations.

Retailers Urge Coal Institute

Efforts are being made by officers of the National Retail Coal Merchants Association to obtain the co-operation of other organizations concerned with the coal industry in early consideration of the proposal for organization of an institute embracing all phases of the industry to handle common problems.

The retail dealers and the anthracite operators have committees on this subject awaiting action by the wholesale dealers and by the bituminous operators.

It is hoped by the retailer's organization to have committees representing all branches of the industry functioning by the time of the next annual convention of the Retail Coal Merchants Association, which will be held in Bluefield, W. Va., June 4, 5 and 6, although it is not believed that it will be possible by that date to have concrete plans for the proposed institute perfected.

Officers of the retailers' association have just begun consideration of the program for the annual convention and details have not yet been arranged. One of the subjects to be given major attention at the convention will be coal legislation in Congress and in individual states.

Trustees to Run Business of Jewett, Bigelow & Brooks

A trusteeship has been effected to conduct the affairs of Jewett, Bigelow & Brooks, with mining and operating offices in Cincinnati and general offices in Detroit. This was the result of conferences held in Cincinnati beginning Jan. 28 and continued for several days. A. McD. England, of the Logan Hardware & Supply Co., Logan, W. Va.; M. E. Brown, Sterling Hardware Co., Hazard, Ky.; Ray Moss, Moss Stores Co., of Pineville, Ky.; John S. Storrs, Storrs-Schaefer Co., Cincinnati; A. T. Siler, attorney, of Williamsburg, Ky., and W. F. Courtney, of Armour & Co., Chicago, have been named as trustees for the creditors and the J. B. B. corporations have agreed to vest in E. L. Douglass, vice-president and operating manager, full power to conduct the business on behalf of the corporation.

The situation was forced through a cloud that has been hanging over the company since it entered an export deal in 1920-21. Jewett, Bigelow & Brooks own or control the following companies: Hazard Jellico Coal Co., First Creek Mining Co., Guyan Mining Co., Varilla Mining Co., Pine Ridge Coal Mining Co., Bradley-Jellico Coal Co., Kimberly Mining Co., Roth Coal Co., Black Joe Coal Co., Jaybee Jellico Coal Co., J B Blue Gem Coal Co., No. 182, J B Elkhorn Coal & Land Co., J B Straight Creek Coal Mining Co., J B B Pocahontas Coal Co., J B Hickory Cannel Coal Co., J B Harlan Fox Coal Co., the Richfield Coal Co. and the J B Stores Co.

Officers of the Jewett, Bigelow & Brooks Co. are well satisfied with the turn that has been taken in the affair and believe that it will only be a reasonable length of time before the whole of the situation is clarified. They point to the fact that there has been an element of doubt existing for some time which will be entirely done away with in the event that the trusteeship reaches the happy conclusion which has been bespoken for it.

N. C. A. Appoints Committees

The National Coal Association has appointed a committee to study Senator Oddie's bill for the establishment of a department of mines and mining, composed as follows: J. G. Bradley (chairman), president, Elk River Coal & Lumber Co., Dundon, W. Va.; D. B. Wentz, president, Stonega Coke & Coal Co., Philadelphia, Pa., and A. M. Ogle, president, Vandalia Coal Co., Terre Haute, Ind.

C. E. Bockus has been chosen by President Brydon to head the committee which, in conjunction with similar committees of the American Wholesale Coal Association, and of the National Retail Coal Merchants' Association, will constitute the Commerce Department's advisory committee on coal. D. B. Wentz and D. C. Guthrie are the other two members of the committee. S. H. Robbins, M. L. Gould and Walter Barnum will serve as alternates. Constituted in this manner, it is pointed out, the committee is representative in that it is drawn from Virginia, West Virginia, Pennsylvania, Ohio, Indiana and Washington.

Censure Coal Company for Johnson City Disaster

A verdict censuring the Crerar Clinch Coal Co. for alleged failure to observe all precautionary rules was returned by the Coroner's jury which heard the testimony at the inquest into the explosion which caused the loss of 33 lives at the East Side Mine, Johnson City, Ill., Friday afternoon, Jan. 25.

Practical Pointers For Electrical And Mechanical Men

Accident Hazard Eliminated by Change In Automatic Reclosing Circuit Breaker

AS THE old-fashioned steam-driven direct-current power plant becomes more and more obsolete, the modern underground substation, which may be located near the working face of the mine, will be called upon to deliver not only proper voltage but will be required to render reliable, efficient and economical performance.

Much has been accomplished in a highly satisfactory manner by means of various devices designed to function automatically, but it is probable that the most appreciated piece of automatic apparatus used in the coal-mining industry is the automatic reclosing circuit breaker used to control the direct-current side of the substation equipment. It not only reduces the labor cost of operation but it has complete and accurate control over all the circuits within the mine, and as its functions are governed by the load conditions of these circuits, important equipment is spared many hard bumps that ordinarily would be experienced

upon the reclosing of a manually operated circuit breaker.

One of the most dangerous accidents that may occur when two or more substations equipped with synchronous converters are operated in parallel is the failure of the direct-current circuit breaker to open at a given load, the result being that the load rises to such a value that the alternating-current supply is interrupted. Under these conditions the direct-current side of the converter would be left directly across the line and if the ordinary type of manually operated breaker is employed a runaway and serious damage to one converter usually results.

The modern automatic reclosing circuit-breaker may have its operating coil in series with the switch of an overspeed device which will de-energize the operating coil of the circuit breaker in time to prevent a runaway under ordinary conditions. It is here, however, that I wish to bring out a point: The conditions are not always ordinary, and serious troubles consequently result.

Probably the most popular automatic reclosing circuit breaker now used in the mining industry is the one manufactured by the Automatic Reclosing Circuit Breaker Co., of Columbus, Ohio. It is some of their old style breakers that I wish to use for an example—types AA and ARL. As all such automatic breakers are based on a similar principle a like weakness may exist in other makes. However, I do not wish the readers of this article to confuse these types with any of the later models, which give almost perfect satisfaction in operation.

Many old type circuit-breakers are still in service, performing in a most satisfactory manner, and are entirely too valuable to discard for the later types. In my experience I have never known one of them to fail electrically, and rarely have they failed mechanically. Some of these mechanical failures, however, might result disastrously to the generator. It is the object of this article to show how these breakers may be changed to make the liability of such failure more remote.

Referring to Fig. 1, it will be noticed that the breaker is closed through the mechanical action of the plunger. (1) by lifting the plunger pin (2) until the

Fig. 2—New Plunger Pin Attachment

The extra weight of the plunger assists in opening the breaker under all conditions.

same comes in contact with the roller (3) the roller arm (4) is brought parallel with the top of the main body casting (5) and the breaker is found to be in a closed position.

As long as the surface on which the roller around (6) engages is kept smooth and the eccentric bushing (7) is properly adjusted there is no question but that this type of breaker will function properly, but when stations are isolated underground without an attendant, these little items are likely to be in need of attention quite frequently, and as a result the general wear that should be cared for by adjusting the eccentric bushing permits the arm (4) to raise above its proper position, which is parallel to the body casting, until it acts as a fixed prop, and even when the operating coil (8) is de-energized by the operation of the overspeed device the breaker remains in a closed position after the plunger (1) and plunger pin (2) have returned to the normal position occupied by them when the breaker is open. This condition probably would result in a runaway and considerable damage.

A quick, reliable method to prevent such an occurrence is as follows: Remove the plunger (1), plunger pin (2) and the roller (3)—Fig. 2 gives the required dimensions for a plunger pin that may be substituted for items 2 and 3 in types AA and ARL of a 600-amp. breaker; other capacities may be de-

Fig. 1—Automatic Circuit Breaker

The plunger pin is redesigned so as to prevent the breaker locking closed when the operating circuit is cut open.

terminated accordingly. Now take the plunger (1); center, drill and tap it to accommodate the pin shown in Fig. 2; place the new plunger pin in the opening left by the pin (2) and screw the plunger on the pin until its shoulder is firmly butted against the top of the plunger, then insert the pin formerly in the roller (3) into the hole of the new plunger pin, reassemble the parts and adjust the breaker. The function of the new pin is to pull the roller arm (4) down when the operating coil is de-energized, regardless of any slight change in the position of the roller arm. It is obvious that the new plunger pin will permit the weight of the plunger to act upon the arm with a jerk, this action being assisted by the pull of the torsion spring (9).

To my knowledge one coal company in eastern Ohio has nine of its substations equipped with old-style breakers arranged as described, and results so far have been very satisfactory.

ROYCE L. GRIMES,

Electrical and Chemical Engineer.
Piney Fork, Ohio.

Keeping the Rock Drill Fit

Rock drills, like all other equipment, need care and attention. The very nature of the work of the drill has made it necessary that all parts be ruggedly constructed, and for this reason the parts inherently withstand much abuse and require but little maintenance. They must be given a reasonable amount of repair, however, and it is essential that it be carried out with due consideration of the function of each part.

The proper maintenance of the drill requires, in the first place, occasional inspection, which when carefully made will disclose any undue wear, damage or imperfect operation of any part. Occasionally, the drill should be taken apart and given a thorough cleaning, preferably with kerosene. After being dried all parts should be reassembled and oiled. In the wet types of drills, if water leaks past the packing around the water tube it will wash away the lubricant. This quickly results in wear on the rifle bar and piston. For this reason it is advisable before assembling to test for leakage by placing the thumb over the end of the tube and turning on the water pressure. When water tubes are renewed, a brand new rubber tube should be used.

The drill shown in the illustration is designed so that the side rods are equipped with cushion springs which hold the different parts together. Both rods should therefore be tightened up to the same tension to prevent breaking the front cylinder head, back head or other parts.

It must be remembered that when the hammer is in operation the steel holder is not a shock absorber and if the hammer is not held close to the drill steel the blow of the piston will be transmitted to the holder rather than to the steel.

Referring to the accompanying illustration, the following vital parts always should be considered:

(a) Broken pawl springs will wear out rotating device. Examine before assembling.

(b) If cylinder front head washer is worn, insufficient guide is provided for front end of piston. When piston hits the steel, side strains and vibrations are set up, resulting in piston leakage.

(c) Examine striking end of piston. If the end is unevenly worn or is chipped or spalled, it indicates shanks of steel are bad. Square end of piston, then be sure shank end of every steel is square, as one uneven, poorly made shank may ruin the piston.

(d) Temper shanks in oil. Grind end smooth and square. Never temper shanks in water or they will be hard and brittle, resulting in increased breakage of steel and piston.

(e) Renew rotation sleeve bushing when worn. When bushings wear large at either end, they allow the steel to wobble. This makes piston hit edge of shank instead of the flat, square end. A gage to be used to determine when the sleeve is worn to the renewal point may be easily obtained.

Rock Drill for Mining Service

The hammer action of a drill makes it necessary that each part function properly. An incorrectly operated drill will soon cause much damage.

(f) Be sure shanks are of proper dimensions. This will give full power of piston blow. If shanks are short, piston will strike front head washer, resulting in breakage of through rods.

(g) Fill lubricator often with proper grade of liquid grease.

(h) Be sure to blow out hose well before connecting to air throttle.

(i) Properly made, correctly tempered and sharp bits will increase the drilling speed. Allow the steel to cool after forging and then reheat for tempering.

Nature and Composition of Insulating Varnishes

Insulating varnishes may be described as liquids of varied color and consistency, composed of a useful semi-solid part, or "base," made up of resins, asphalts, pitches, drying oils, driers, etc., and a solvent in which this base is dissolved or uniformly incorporated. They are used to fill or cover paper, fabric and other materials, thus improving their physical and insulating properties by replacing the occluded air with a dielectric of higher order or helping to maintain the constancy of

the initial insulation of the parts treated by affording an impermeable covering to these parts through which deleterious substances cannot pass.

They should be of such nature that, after application, they may be changed from the liquid to the solid state, or practically so, by some convenient means such as heat. In order to perform their function they must possess numerous and varied qualities, both before and during setting as well as in their subsequent useful life.

Spirit varnishes consist of varnish gums or resins dissolved in a suitable solvent, usually alcohol. The varnish may or may not be colored by the addition of dye, but it usually contains ingredients to improve the flexibility. These varnishes dry by the evaporation of the solvent, which leaves a film of the gum on the surface to be coated.

Some consider spirit varnishes more as finishes than as insulating varnishes, for their principal use is as a finishing coating over other insulating varnishes. In some applications, however, they are used for insulating purposes where little flexibility and great binding and cementing properties or exceptionally quick dry are required.

Oil-type insulating varnishes consist of varnish gums or resins in combination with vegetable drying oils (generally China wood oil and linseed oil) dissolved in a suitable thinner, usually petroleum naphtha. In the black varnishes the clear gums are replaced with asphaltic materials or pitches. The oil-type varnishes dry by the evaporation of the solvent and oxidation of the vegetable oils. The drying time is governed by the proportion of gums and oils and by the quantity of oxidizing agents or driers in the varnish. The greater the proportion of oils, the longer the drying time. They are classed as air-drying or baking varnishes, depending on the method of drying and length of drying time.

Some of the quick air-drying black varnishes may contain no drying oil. Such varnishes are neither oil type nor spirit varnishes and may be termed "asphaltic varnishes," consisting of an asphaltic base and solvent which may be a petroleum or coal-tar distillate or a mixture of the two.

In the manufacture of spirit varnishes the gums are cut cold in the solvent, while the oil type varnishes and asphaltic varnishes are made by fluxing the various ingredients together in a kettle at a high temperature. Variations in the physical characteristics are produced by variations in the formulas and in the heat treatment.

Liquid varnish changes to a solid by drying, and during this process it passes through all the intermediate stages. To thoroughly understand the characteristics of a varnish it is necessary to study it both in the liquid and solid states.

It has not been possible to combine all the desirable qualities in one product and for this reason many distinct types of insulating varnishes have been produced in which certain qualities have been improved at the expense of others to make them most suitable for specific uses. Many of these characteristics are interdependent while others are opposed and cannot be combined.

Undercurrent of Confidence in Market for Soft Coal as Result of January Trade Trend

The trend of business in the first month of the year has given the soft-coal market a feeling of greater confidence. The Geological Survey shows larger bituminous-coal production at this period than has ever been experienced at this time of the year. There is slightly more activity although it has not yet been reflected on prices. The anthracite market is suffering from weather conditions and is not as active as it should be at this time of the year. Bituminous coal consumers are coming into the market with more regularity and that much quiet buying is being done is shown by the production figures, which are being maintained around 11,500,000 net tons weekly.

Consumers are breathing a little easier now that it is known what the soft-coal miners will demand of the operators when they meet at Jacksonville next Monday. No considerable change in prices is expected unless there should be a suspension about April 1, and with the huge reserves on hand it would be several weeks before the market would feel its effect.

End of British Strike Blasts Export Hope

The ending of the British railway strike knocked on the head whatever hopes coal exporters held in that direction. The shortness of the cold spell which covered most sections of the country a couple of weeks ago was reflected in the various markets, and while there continues a good demand for bituminous domestic coals it is not as active as it was last week.

Coal Age Index as of Feb. 4 registers 187 with an average price of \$2.26, there being no change from the previous week.

Business in the Middle West is only fair. Stocks in the retail yards were greatly reduced during the low temperatures and many new orders were placed. Demand for domestic coals is fair and there has been

enough cold weather to keep dealers busy. Domestic demand at St. Louis is easier, and little is doing in the anthracite and smokeless trade. Demand for western Kentucky coals is somewhat improved, with prepared sizes in fair call. The outlook for bituminous at the Head-of-the-Lakes is encouraging. Reserves are being put in and the various industries show improvement.

Ohio Not Encouraged at Outlook

Filling of orders placed during the recent cold wave keeps the Ohio trade moving, but the ultimate outlook is not encouraging. Retail dealers' stocks are not large and dealers are not inclined to buy heavily. The steam trade is quiet, though the smokeless coals are moving freely. Transportation in some sections is a trifle slower, but prices are generally maintained. There is a little more activity at Pittsburgh but prices show practically no change and weather conditions have left stocks larger than normally on hand. In New England there is a belief that the resumption of the 1917 wage scale in the New River district probably means a base price of \$4.75 per gross ton f.o.b. vessel Hampton Roads, the same as during the early part of 1917. The condition of the market at New York is reflected in the bids received by the U. S. Shipping Board in that city last week for about 1,700 gross tons of bituminous coal, the prices ranging from \$4.98 to \$5.99, alongside vessel, or on a basis of about \$1.74 to \$2.63 f.o.b. net ton at the mine.

Demand for domestic sizes of anthracite is not exceedingly active. Stove and chestnut coals continue to be the most in call, but these are not sufficiently short to create any trouble. Some independent producers find it difficult to keep their product moving unless they quote close to the larger company price lists. There has been

a marked falling off in sales of anthracite in the Duluth market.

Output of bituminous coal is estimated by the Geological Survey to have been 11,599,000 net tons during the week ended Jan. 26, a decrease of about 23,000 tons when compared with the previous week. During the same period 1,782,000 net tons of anthracite was produced, a decrease of 102,000 tons when compared with the previous week.

Midwest Business Fair

Domestic business throughout the Middle West continues fair with only a few cancellations of purchases made during the blighting cold spells of two and four weeks ago. There has been enough winter to keep the retail yards active and not enough to hamper railroads much. The result has been a smooth flow of large coal but no noticeable drop in its price, for a large number of the Illinois and Indiana mines are still down and no doubt will stay down.

Steam coal went into the inevitable sag during the past

few days, with only a small upward turn at the end of last week. While the dominating producers of Franklin County maintain their circular quotation of \$1.75@ \$1.90 on screenings, a good deal of their output moves sluggishly. Central Illinois small coal has been down to \$1.25 but at the end of the week was reasonably firm at a nickel better than that. Western Kentucky screenings, always on hand for any buyer, is below a dollar on the Chicago market. Eastern coals have a hard time in the Midwest territory except good smokeless. Pocahontas mine-run sticks at \$2.50 and lump at \$3.50 with a good deal moving in.

St. Louis Slows Up

With weather above freezing in St. Louis the domestic demand has eased up and there is little or no demand locally for carload steam, although wagonload steam continues good. Country domestic is just fair as is the demand for cheaper grades, in St. Louis. It is almost impossible in some sections to move Franklin County coal. Country steam has eased up somewhat and the situation is one that makes it difficult to move anything. There is nothing doing in anthracite or smokeless trade and very little coke is mov-

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

	1924	1923
Index	Feb. 4 187	Jan. 28 187
Weighted average price	Jan. 21 182	Feb. 5 312
	\$2.26	\$2.26
	\$2.20	\$3.78

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally, shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

ing. Some dealers are cutting the price of Carterville from \$8 to \$7.50, especially in South St. Louis, to favored customers. Dealers report a good supply of everything on hand.

Kentucky Fairly Active

Demand for western Kentucky coal has been somewhat better, with a good movement to the Southern, Western and Central states, and as far north as Michigan. Prepared sizes have been in fair demand. Steam coal also has been moving quite well, but production of screenings has been heavy enough to break the prices somewhat, as evidenced by screenings having been offered as low as 80@85c. a ton. The bulk of the movement is at 90c. to \$1.15.

Operating time has been increasing in a number of mines, and some that have been down are resuming operations, with others planning to do so. A few operators report better running time, and with car supply favorable, the outlook is for good business over the next sixty days, as stocks in many sections have been greatly depleted. Prepared prices promise to continue at about today's figures, which range from \$1.75 on small nut to \$3 for best 6-in. block, with mine run at \$1.50@1.90.

Northwestern Market Softens

Despite mild weather at Duluth, which has reduced the market, prices of screenings have taken an upward surge in the past week, which points to a considerably strengthened market. The fall off in anthracite sales has been most marked and the bituminous decrease has been in the nature of a slackening rather than a general letdown.

Duluth prices, with the change in screenings, are as follows: Kentucky lump, \$7.25; run of pile, \$6.50; screenings, \$4.50; Youghiogheny lump, \$6.50; run of pile, \$5.50; screenings, \$4.25; Hocking lump, \$6.25; run of pile, \$5.25; screenings, \$3.75@4; Splint lump, \$6.75; run of pile, \$5.75; screenings, \$4.50; Pocahontas lump, \$9; run of pile, \$6.50; screenings, \$5.50. Coke is still at \$10.50 and briquets at \$10. The market in anthracite is the same as last quoted.

The Head-of-the-Lakes outlook in bituminous coal is encouraging. Factories are putting in stocks and the independent iron mines are starting mining with a vim. The Steel Corporation asserts that it has enough coal on its private dock to last through the summer, and this is giving heart to the independents to continue work, as it looks as if the Corporation were planning on a full year. The general impression at Duluth is that there will be no strike this year.

The Milwaukee coal market is very active, both in a wholesale and retail way, and stocks are being drawn upon quite heavily. The protracted cold spell forced many dealers in the interior to buy. Prices hold steady. Jobbers are finding it extremely difficult to get high-grade Eastern soft coal—splints and Pocahontas—the market in the East being sold up and with orders ahead, so that rail supplies of this class of coal will not be available until well into February.

Western Situation Is Spotted

Mines through the Southwest still are working virtually full time, although a surplus of both lump and screenings again has begun to accumulate. Saturday, Jan. 26, the Pittsburg district had its largest payroll in more than two years. There has been no change in quotations on Kansas coal. Lump still is \$5; nut, \$4.25; mine-run, \$3.50, and screenings, \$2.25.

In Colorado the market has slowed down slightly as compared with the past few weeks, due to the warm weather. However, the operators are having no difficulty in disposing of all of the coal mined.

Prices continue to remain unchanged and the present supply of labor is sufficient. Transportation and car supply have been good throughout the state except in Routt County, where weather conditions have prevented considerable movement of all commodities.

Utah business is slow. The state is averaging little more than two days a week and mines are shutting down because they cannot dispose of intermediate sizes. Stocks are low in retailers' yards but cold weather is breaking and no rush for coal is expected. Industries are not buying much.

Demand for Domestic Coals Easier in Ohio

There has been a marked recession in the demand for domestic coals in the Ohio markets, due to milder weather. Orders booked for delivery in the Columbus market, however, will mean considerable activity in the southern Ohio coal fields for several days, but in the absence of continued cold weather the outlook is not encouraging. Retail dealers are not buying heavily and their stocks are not large; prices are firm. The demand for Pocahontas and other smokeless varieties is strong. Steam trade is quiet. The falling off in quotations for screenings is attributed partly to increased production during the period of better lump production and also to several large users refusing to take on more tonnage. Production in the Hocking valley has increased to between 25 and 30 per cent of capacity. Some large consumers are increasing their reserve stocks. Railroads are making inquiries, while iron and steel plants are buying slightly more than current needs.

The Southern Ohio Coal Exchange reports for the week ended Jan. 19 show an output of 213,273 tons from 446 mines having a full-time capacity of 681,400 tons. Of the shortage "no market" was responsible for a loss of 422,308 tons.

At Cincinnati a slowing up in transportation and continuance of the strong positions in prices in spite of milder weather are the outstanding features of the market. Coal that had been taking five days from the mines in south-eastern Kentucky to Chicago has been slowed up to three weeks and then the Pennsylvania lines notified Kentucky shippers that they would be forced to refuse acceptance of cars at interchange points at Cincinnati. In the high-volatile market the demand for domestic and slack is the strongest. The February "circular" put out by the smokeless companies shows \$3.50 for lump and egg; \$2.50 for mine-run, but no set figure for screenings. These were scarcely in the mails before Chicago and Western points started bidding \$4 for "car numbers" and \$3.75 for spot prepared. Retail dealers believe that unless there is a tremendous change, present prices will hold until April 1. These are \$9 to \$10 for Pocahontas lump; \$7 for mine-run; \$8@\$.25 for bituminous lump and \$4.50@\$.5 for slack.

Operators in the Cleveland market say that demand from both steam consumers and retail yards continues fair, with no apparent effort to obtain much more than current needs. Industrial plants have from four to six weeks' supplies on hand. Consumption is kept down through many lines of industries operating only four or five days a week. Distress coal is not so abundant as it was a week ago in view of the troubles experienced by shippers in disposing of recent shipments on open consignments.

Pittsburgh Market Somewhat More Active

Activity in the Pittsburgh market is a trifle heavier than a week or two back and the turnover since the first of the year has in general been distinctly heavier than during the last few weeks of 1923. Consumption of coal in the territory normally tributary to the Pittsburgh district is all that could be desired, except in the case of domestic coal, the prolonged mild weather having left householders' stocks larger than they normally are at this time of the year. The steel industry is operating at about 25 per cent better rate than during December, with a corresponding increase in coal consumption. The chief difficulty in the district is the competition from nearby non-union fields, which is apparently growing more severe. Operators in the district remain silent as to whether or not they will attend the wage conference at Jacksonville next week, no formal statement having been issued regarding the letter of Secretary Hoover. Reports from central Pennsylvania indicate a better demand. During the week ended Jan. 26 loadings totaled 15,340 cars, as compared with 15,247 during the previous week.

There is a light demand for soft coal at Buffalo, consumers ordering only for current needs.

New England Reports Few Sales

In New England eyes the only outstanding feature of the past week was the resumption of the 1917 wage scale in the New River district. It means, probably, a \$4.75 base price per gross ton f.o.b. vessel at Hampton Roads, approximately the same basis that carried through the early part of 1917. The few sales that have been made since February came in have been at around \$5 for spot shipment, with a net return to the operator of about \$4.75. Inquiry here is still very light, and buyers show interest in quotations only for their bearing on spring prices.

We hear of no material increase in production. Several

of the smokeless agencies are practically without coal on hand at the piers, and there continue to be borrow and loan transactions among the different shippers to clear what tonnage reaches the piers. There are still some unshipped balances due offshore, and these together with contracts coastwise are absorbing nearly all the present restricted east-bound movement of Pocahontas and New River.

At this end for distribution inland there is practically no change in the market. Prices on cars range \$6@\$.625 per gross ton, but reserves are large in almost every instance and new purchases are for only scattering amounts. Prices of Southern coals will have to advance very materially before there will be any demand for Pennsylvania coals all-rail in the territory easily accessible from tide-water.

Little Improvement in Seaboard Markets

There are a few signs of improved conditions along the seaboard. At New York inquiries are a little more numerous and there has been a trifle better buying, but not sufficient to change current prices: The Philadelphia trade believes that January business was an improvement over December and that this month's buying will be an improvement over last month. The improvement in buying at the New York and Philadelphia markets may be due in part to a fear that there will be a suspension, even though there is a feeling that present prices will continue, notwithstanding the fact that the miners are asking for a long-term agreement and not an increase in wages. The Baltimore market is flat and no encouragement is seen. Interest is centered in the export demand.

The strike of the Nova Scotia miners has already been reflected in the Baltimore market, one steamer carrying about 7,000 tons of coal having left there for Halifax, according to reports. During the first twenty-eight days of January cargo coal amounting to 61,675 tons was dumped at Baltimore, as well as 3,491 tons of coke. The settlement of the British railway strike ended many inquiries which had been made regarding foreign shipments, but some business is reported as having been closed for South America.

Hard-Coal Market Unresponsive to Weather

Weather conditions have had no effect on the hard-coal situation. Retail dealers are well supplied and a few days of real cold weather had little effect. Orders are delivered promptly and production is sufficient to keep the market well supplied and movement rapid. Consumers are beginning to guess as to what will happen on April 1, and with that in view are not likely to buy any more coal than they actually need between now and then. Egg and pea sizes are the easiest, though the demand for stove and chestnut is not much more active. In Baltimore the market is quiet and, due to the mild weather, retail dealers report an increasing call for wood and briquets. The steam coals in the various markets are in better shape. The tonnage has been reduced and quotations for all three sizes are a trifle firmer. Barley is the shortest.

The market for furnace coke stiffened last week. A contract for about 5,000 tons a month during this and next month has been closed at \$4.25, with other contracts reported as having been closed at about the same figure. There also have been several inquiries for the second quarter. Floating supplies of spot furnace coke under \$4 have practically disappeared. Foundry coke continues easy at \$5@\$.50.

Foreign Market And Export News

British Coal Output Slumps as Result of Rail Strike; Dock Men Threaten

Production of coal in Great Britain during the week ended Jan. 19 took a decided drop as a result of the railway strike, amounting to 2,848,000 tons, which is a lower level than for any week since July 8, 1921, when the output was 2,355,000 tons. The output during the week ended Jan. 12 was 5,747,000 tons.

As soon as the railway strike was ended and even before the men had returned to work the leaders of the dock workers instructed the members of that organization to stop work in all ports of Great Britain on Feb. 16 unless their wage demands are satisfactorily settled.

Contrary to the general expectation, the Welsh coal market has taken a definite turn for the better, in spite of the refusal of the tipplers to operate the third shift. The result of this refusal has been considerable delay in shipment.

In anticipation of labor trouble here soon and in America about March, foreign buyers are showing a tendency to lay in stocks; as a consequence many of the pits are well booked into March. French and Italian buying is becoming heavier, and fair sized quantities have been sold to the Scandinavian state railways.

The feeling among the miners for terminating the wage agreement probably is stronger in Wales than elsewhere in the United Kingdom. It is estimated that from 80 to 90 per cent of the workers in the Welsh coal mines are in favor of the adoption of this course.

Orders for prompt shipment are fairly numerous in Newcastle, though the deliveries of German reparation coal into France and Belgium are proving a handicap. The Norwegian State Railways have placed orders aggregating about 35,000 tons of steams for delivery before March.

French Coal Market Fair

The French Government has taken further steps to obtain from the mine owners a reduction from the last advance in selling prices made as a result of wage increases. No announcement has yet been made as to the outcome of negotiations. The coal market continues fair.

Owing to the cold weather prevailing in Belgium France is now receiving but few offers for sized products. No official change has been made in prices, while rebates are granted in some instances. Total arrivals of coal from Cardiff during the week ended Jan. 23 amounted to 250,000 tons.

Better Outlook at Hampton Roads

Business at Hampton Roads was more brisk last week, though prices weakened slightly in the face of increased surplus at tidewater. Coastwise trade showed improvement and some pick-up was noted in foreign business.

Dumpings at the Norfolk & Western piers led the field easily, and inquiries in all branches of trade increased, with shippers looking forward to continued improvement throughout the entire trade.

Improvement in general shipping, resulting in brisker bunker trade, was reported, with generally steadier conditions and more optimism. The tone of the market was firm and the outlook promising.

Traffic News

To Argue Hard-Coal Rate from Buffalo Feb. 18

The case which has just been heard in Minneapolis before Examiner Money for the Interstate Commerce Commission on the opposition to the freight rate increase on hard coal from Buffalo to Minneapolis of \$1.66, will be argued in Washington Feb. 18. County Attorney Olson, of Minneapolis, expects to argue the case before the commission at that time. It has been hinted that a decision probably will be reached by April 1. In the hearing just closed, Secretary Ellis, of the dock association, testified that he did not expect the dock trade to increase prices of hard coal if the joint rate on hard coal were withdrawn, but he did expect them to ask for a lower rate on lake and rail if the all-rail rate were not increased, since they claim the lake and rail rate is not in line with the present all-rail rate.

W.Va. Operators Prepare Data In Lake Rate Fight

In preparation for presentation before the Interstate Commerce Commission of the case of West Virginia operators who seek an adjustment of lake freight rates a meeting of officers of the Northern West Virginia Coal Operators Association and of the lake freight-rate committee was held at Fairmont, W. Va., during the latter part of January, attended by E. J. McVann, of Washington, who has been retained as special counsel by the association. At the conference officers and members of the committee who have been busily engaged in collecting data, submitted the information to Mr. McVann to be used in support of the claims of northern West Virginia operators for an adjustment of freight rates. Serving as members of the lake freight committee for the Northern West Virginia Association are E. W. Ziler, of Elkins; J. M. Orr and A. L. White, of Clarksburg.

Mr. McVann, for the association, has already submitted a petition to the Commerce Commission requesting that northern West Virginia operators be permitted to intervene in the case of the Pittsburgh Vein Operators Association against the Ashland Coal & Iron Ry. and others, that case also involving lake freight rates.

Promotions on B. & O.

Archibald Fries, vice-president in charge of traffic and commercial development of the Baltimore & Ohio R.R., has announced the following appointments, effective Feb. 1, 1924: W. W. Blakely, general freight agent, Pittsburgh, Pa., is appointed assistant to general freight traffic manager, with headquarters at Baltimore, Md.; John

H. Carroll, Jr., general freight agent, Philadelphia, Pa., is appointed general freight agent at Pittsburgh, vice Mr. Blakely, promoted; Samuel House, general freight agent, Baltimore, is appointed assistant freight traffic manager, with headquarters at Baltimore; C. S. Roberts, assistant general freight agent, Baltimore, is appointed general freight agent at Baltimore, vice Mr. House, promoted; George S. Harlan, assistant general freight agent, Baltimore, is appointed general freight agent, with headquarters at Philadelphia, vice Mr. Carroll, promoted.

Lower Railroad Rates for Coal From Indiana Mines In Sight

An order that railroad companies hauling coal from Indiana mines to Indiana points shall reduce their rates is in course of preparation in the offices of the Public Service Commission and is expected to be promulgated next week.

The order has for its basis, it was learned, new schedules that will, according to representatives of the carriers, cut railroad revenues in Indiana more than \$500,000 a year but which will be of benefit to industries, public utilities and other large consumers of coal. Whether retail coal dealers will pass any of the lower transportation costs on to domestic consumers in the way of reduced prices is not known.

Association Activities

Sequent on a two-day meeting of the Executive Committee of the American Wholesale Coal Association the **Philadelphia Coal Club** held its annual banquet on Jan. 31 at the Bellevue-Stratford, Philadelphia. Noah H. Swayne presided and the speakers were Charles L. Dering, president, American Wholesale Coal Association; I. R. Williams, of the Philadelphia Bar, and Dr. J. T. Holdsworth, of the Pennsylvania State Land Bank. The first spoke on the essential equality of the coal industry with other industries, the second on the threatened invasions on the Constitution and the Supreme Court, and the third on the importance of avoiding special legislation. Noah H. Swayne, of the Noah H. Swayne Co., was re-elected president; Pratt Thompson, Lehigh Coal & Navigation Co., vice-president, and Charles K. Scull, secretary-treasurer. The latter is secretary-treasurer also of the Philadelphia Coal Exchange. The directors elected were W. E. Bernard, J. W. Mason, John Haslett, H. C. Pearson and W. J. Jennings.

One of the most successful and best attended annual meetings in the history of the **Northeast Kentucky Coal Association** was held recently at Ashland. Reports made by officers and committees of the association went to show that a great volume of constructive work beneficial to the operators in the Big Sandy Valley has been accomplished during the year. J. G. Bradley of Dundon, president of the West Virginia Coal Association, delivered an interesting address on "Labor Relationship," explaining the material benefits to be derived from co-ordination and co-operative effort on the part of individual operators with district associations and through the district associations with their respective state organizations and the National Coal

Association. W. H. Cunningham, of Huntington, delivered an interesting address on the subject of legislation affecting the industry. Another speaker both at the business session of the association and at the banquet was Harry L. Gandy, secretary of the National Coal Association, who urged closer co-operation on the part of operators with district associations and through their district associations with state associations and the national association. At the banquet he declared that the fight of coal against control by the state was the fight of all industries and business. The following officers were elected: C. W. Connor, of Esco, Ky., president; Cadwalader Jones, of Wheelwright, Ky., first vice-president; O. P. Chafield, of Dunleary, Ky., second vice-president; N. M. White, Sr., of Prestonburg, Ky., treasurer. The above officers and the following operators become the executive committee of the association during the year: Henry LaViers, of Paintsville, Ky.; C. H. Beidenmiller, of Huntington, W. Va.; A. M. Campbell of Ashland, Ky.

The Committee on Reorganization of the **Central Pennsylvania Coal Producers' Association** has reported the creation of the following committees to carry on the work of the association during the coming year: Legislation, B. M. Clark, chairman; Traffic, Charles O'Neill, chairman; Labor, officers of the association; Public Relations, president and secretary of the association; Statistics, W. A. Jones, chairman; Classification of Coals, Rembrandt Peale, chairman; Mining Methods, Mechanical Machinery and Power, J. Wm. Wetter, chairman; Fire Insurance, C. B. Maxwell, chairman; Finance, Pearle (chairman), Boucher and Coleman; Auditing, Caseley (chairman), Maxwell and Scott.

The **Hazard Coal Operators Exchange** held its annual meeting at the Lafayette Hotel, Lexington, Ky., on Jan. 25, at which time J. E. Johnson was re-elected president and secretary. The principal business was in connection with reading the reports of the president-secretary and hearing various committee reports, along with adoption of a few resolutions. Henry L. Gandy, Executive Secretary of the National Coal Association, talked on general conditions in the coal trade, and J. D. Battle, traffic manager of the National, talked on transportation conditions and increased efficiency of the railroads.

Obituary

Paul W. Gillham, aged 43, died at Christ's Hospital, Cincinnati, Jan. 25. Mr. Gillham was a graduate physician and practiced until 1909 at Botkin, Ohio, when he entered the coal business. At various times he was associated with the Burlington Coal Co., the Wyatt Coal Sales Co., the Thomas L. Mordue Coal Co. and the Boone Coal Sales Co. He was one of the three partners who started the MacBard Coal Co. in 1916. About a year ago, realizing that his health was failing, he retired and spent the time in the north woods of Michigan, returning to Cincinnati some four or five weeks ago. He was a son of R. P. Gillham of the Campbell's Creek Coal Co. and two of his brothers are connected with that organization.

Coming Meetings

Rocky Mountain Coal Mining Institute, Winter meeting, Feb. 13-15, Albany Hotel, Denver, Colo. Secretary, Benedict Shubart, 521 Boston Bldg., Denver, Colo.

American Institute of Mining and Metallurgical Engineers, Annual meeting Feb. 18-21, 29 West 39th Street, New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

Northern West Virginia Coal Operators Association, Annual meeting Feb. 12, Fairmont, W. Va. Secretary, J. O. Caldwell, Fairmont, W. Va.

Upper Potomac Coal Association, Annual meeting March 3, Cumberland, Md. Secretary, J. F. Palmer, Cumberland, Md.

Canadian Institute of Mining and Metallurgy, Annual meeting March 5-7, King Edward Hotel, Toronto, Ontario, Canada. Secretary, G. C. Mackenzie, Drummond Building, Montreal, Quebec, Canada.

New England Coal Dealers' Association, Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

News Items From Field and Trade

ALABAMA

The State Board of Examiners, which held a session Jan. 21-24, issued certificates of competency to twenty-three applicants as mine foremen, first-class; two for positions as second-class mine foremen, and eleven passed the test required to hold the position of fireboss in Alabama coal mines.

Promotions recently announced by the Woodward Iron Co. elevated J. A. Long, assistant general manager, to the position of general manager, and William Miller, superintendent of the coke plant, was promoted to be assistant general manager. Mr. Miller was succeeded as manager of the coke department by Harry Ross, formerly assistant superintendent.

ILLINOIS

The Southern Gem Coal Corporation receivership is now in effect for the second time, after the concern had once had it lifted on technical grounds. The original receivers, Charles E. Thomas and W. S. Wilson are in charge of the offices and property.

The mine at Tamaroa owned by the Little Muddy Coal Co. has a record of having worked every day during January. The shaft produces about 700 tons daily.

Thomas Hunter, a former employee for the Union Colliery Co. at Dowell, has accepted a position as state mine inspector in the Springfield District.

Work was resumed Feb. 4 at the McClinck mine of the Crerar Clinch Coal Co. at Johnson City. The plant has been shut down since the explosion of Jan. 25 in which 32 men died.

Miners employed at the mine of the Gallatin Coal & Coke Co.'s mine at Equality are now operating the mine on a co-operative agreement between the receiver for the company and officials of the local mine union. The drifts of the mine were filling with water and getting into such shape that it soon would have been impossible to repair the damage when the miners voluntarily went into the mine and repaired the damage. They then went to the receiver, Charles H. Guard, and signed an agreement to pay all the expenses of running the mine and a fixed amount for each ton hoisted in return for the sale of the coal. The plan was indorsed by the Circuit Court and also by the miners' union. The contract expires on April 1, 1924.

KENTUCKY

Another wash house bill has been introduced before the Kentucky Legislature to force operators to provide wash houses and hot and cold showers for mine workers. Such a law was enacted in 1920, but contained a provision that the operator would have to install such equipment when 30 per cent of his employees demanded it. A test case of the Beaver Dam Coal Co., of western Kentucky, was decided against the company in the Ohio County Circuit Court, and then carried to the Court of Appeals. On Feb. 28, 1922, the Court of Appeals in a decision, held that Chapter 20, Acts of 1920, was unconstitutional in that it was a delegation of legislative power, which only the Legislature had the right to decide.

The Carnegie Hero Fund Commission has awarded a bronze medal to Porter G. Gish, of Boxville, in Union County, western Kentucky, a mine motorman. He saved 24 men in a Union county mine from smothering or suffocating at Henderson, Ky., on May 26, 1921.

Fire destroyed the general office and store building of the Fordson Coal Co., at Stone, in the early morning of Jan. 30, causing a loss estimated at \$150,000.

A bill under which scrip issued by mining and other companies, would be redeemable every pay day by concerns issuing it to employees, has been favorably reported in the house. Such a bill was passed by both divisions of the Kentucky General Assembly in 1922, was later lost and never enrolled.

A state mining inspection board would be created in Kentucky if a bill introduced by Senator Griffin Keely, of Daviess County, was enacted. The bill provides for creation of a board composed of three practical coal miners, to be appointed by the Governor, and all miners permitted to work in mines of the state would have to pass examination under this board and pay a fee of \$2 each for "certificates of competency." The three board members would receive salaries of \$150 each per month and the bill would carry an annual appropriation of \$12,000. This is another law that is fostered by union labor.

W. B. Gathright, who for a number of years was manager in Louisville, for the St. Bernard Mining Company, has announced connection with the R. C. Tway Coal Co., selling coal at wholesale. Mr. Gathright left the St. Bernard Co. on January 1.

The Ulvah Coal Co., at Bluefield, Letcher County, lost its commissary store by fire on Jan. 28, the loss being \$10,000 with insurance of about one third that amount.

E. E. Lanning, of the Jellico Coal & Coke Co., Louisville, and member of the Horton Coal Co., Horton, was recently at Horton, planning the resumption of work at the company's western Kentucky mine, which has been down for some months.

It is reported that the Henry Ford controlled mines at Banner Fork, near Wallins, are planning to resume on full-time operations about March 1, with the idea of running full for nine months.

According to 1923 Geological Survey reports Kentucky showed a loss of 5 per cent in coke production, in a decline of 22,000 tons to 435,000 tons, whereas other states during the same period showed increases of 13 to 41 per cent. One reason for this has been small consumption in the state and long hauls to market along with development of coal markets consuming the fuel, while a good natural gas supply in the state has made for relatively small gas coke production.

MINNESOTA

Dr. Hans Holzworth, representing Thyssen & Co., of Germany, talked before the St. Paul Engineers' association last week on the lignite of North Dakota. He declared there was a supply of lignite for 700 years, and that by carbonizing and briquetting, lignite could be used for either anthracite or bituminous substitute. A plant is to be established at Richardson, N. D. by the Lignite Coal & By-Products Co., of Delaware, using the Thyssen system.

The Lignite Industries Corporation proposes to set up in St. Paul the first plant in this country for briquetting and extracting byproducts from lignite, before it is shipped to Texas. The machine has been tested in Germany for eight months under actual service conditions.

NEW JERSEY

Again placing responsibility for assuring an adequate supply of coal at reasonable prices at the door of Pennsylvania and the federal government, Governor Silzer sent a special message Jan. 29 urging the legislature to impress the situation on Congress. "Three remedies have been suggested," said the Governor's message. "The first is to call upon our neighbor—Pennsylvania—to adopt such measures as she may deem advisable to control the situation so far as it lies within the power of a state to do so. The second is to urge upon Congress the necessity of regulating the industry, not only to the extent of interstate commerce but also upon the basis that it is an industry so affected with the public interest that the federal government may exercise powers such as are now exercised, by act of Congress, over like industries. The third is to enact such legislation within our own state to deal adequately with the situation after the coal is out of interstate jurisdiction and in the possession of local dealers."

OHIO

H. M. Griggs, manager of the Ore & Coal Exchange, Cleveland, who was recently in Cincinnati, says that there seems little likelihood of contracts being arrived at until the air is clarified of strike talk and labor trouble. He would not venture to name a price at which coal might move, saying that this was a situation that would have to work itself out.

Lathrop & Trotter have opened offices in the Union Trust Building, Cincinnati, and will be the representatives of the Conveyors Corporation of America at this point.

Pittsburgh and Zanesville capitalists plan the development of a 1,000-acre tract near Satillo, which is underlain not only with coal but also clay and sand. The coal will be removed by stripping. The company, which will be chartered soon, is to be styled the Consolidated Coal & Sand Co.

George S. Payne, who has been connected with the Blue Ash Coal Co. since 1913 and who is one of the oldest coal men in the Cincinnati district, announces that he will soon retire from that firm.

Contracts were awarded by the Columbus Board of Purchase for 10,500 tons of coal as follows: J. Miller Coal Co., Columbus, 8,500 tons of nut, pea and slack at \$1.40 f.o.b. mines, this coal to be used by the municipal light plant and the Water Works department. Central West Coal & Lumber Co., Columbus, 2,000 tons of Hocking nut, pea and slack for the garbage disposal plant at \$1.40 f.o.b. mines. All of this tonnage is to be delivered by March 31.

The Central mine, at New Straitsville, employing 107 men, reopened recently after a suspension of several months due to lack of demand. The Gem mine also will soon be reopened.

Several prominent operators from West Virginia attended a meeting held by the Fort Dearborn Coal Co. in Cincinnati Jan. 29 and 30. Among these were Holmes and Quin Morton, of Charleston; Walter Wood, Bill, Tom and Barnes Gillespie and Henry Harmon, all operators, and Harry Hall and George Staymer, of the offices of the company in Chicago.

The Simpson Creek Collieries Co., Cleveland, has been chartered with an authorized capital of 500 shares, no par value designated, to mine and sell coal and coke. Incorporators are Paul J. Bickel, F. S. Whitcomb, Howard L. Barkdull, Edwin H. Chaney and Frank Harrison.

A joint meeting of the Southern Ohio Pig Iron & Coke Association, the Ohio section of the American Institute of Mining and Metallurgical Engineers and the Cincinnati Coal Exchange was held Jan. 28 in the Hotel Gibson, Cincinnati, with 75 members in attendance. "Clean Coal" was the subject that occupied foremost attention during the session, which lasted throughout the day. Standardization of sampling and analysis was suggested as the best means to obtain coal that would burn with the least amount of waste and dirt. The meeting closed with a dinner, at which pictures connected with the coal-mining industry were shown. R. H. Sweetzer, of the American Rolling Mills Co. and president of the Pig Iron & Coke Association, presided at the meeting.

A. E. Frich, secretary to the superintendent of the Ohio Division and other Baltimore & Ohio Ry. experts who have been making an extensive study of maximum efficiency in the use of fuel as applied to the Ohio Division, have announced that a pound of coal moves a ton of freight six miles. The high price of fuel, even for the railroad, has led to an intensive effort at economy and a steady increase in the service to be obtained from every ton. The latest figures, however, have been worked out on a per-pound basis.

The newest and what will be one of the largest ore-carrying vessels on the Great Lakes, the William K. Field, named after the president of the Pittsburgh Coal Co., was launched Jan. 23 at Toledo. The new freighter is owned by the Reiss Steamship Co., of Sheboygan, Wis. The William K. Field is 604 ft. long with a 60-ft. beam, 21.6-ft. draught, and will carry 15,000 tons of coal. The ship will also be equipped to carry a load of 500,000 bushels of wheat. Among those present at the launching were Messrs. Field and Reiss and the following officials of the coal company: J. Donaldson, J. H. Woods, J. B. L. Hornberger and F. J. LeMoyné, vice presidents; C. E. Leshner, assistant to the president; Aaron Westlake, secretary, and Don Rose, general counsel.

PENNSYLVANIA

Herbert Hoover, Secretary of Commerce, has advised members of the Pittsburgh Coal Producers' Association to take part in the wage conference of operators and union officials at Jacksonville, Fla., Feb. 11. The suggestion was contained in a letter to C. J. Goodyear, representing the association. The association refused in 1922 to confer with the union except on a district basis, which the union refused, a strike resulting. Periodic suspension of coal production, Mr. Hoover said, had resulted in high-priced coal, the maintenance of a large number of uneconomic mines, and generally brought about a situation which called for the "real cure of a period of continuous operation under free competition and full movement of coal."

A certificate of incorporation for the merger of three big companies has been approved by the Public Service Commission. The companies involved are the Springfield Mining, the Bloomington and the Springfield companies. The new corporation will be known as the Springfield Coal Mining Co., of Ebensburg, with a capital of \$2,000,000.

M. D. Cooper, of Pittsburgh, assistant general superintendent of the Hillman Coal & Coke Co., in charge of plants in the Connellsville coke region, has his territory enlarged to include Edna Nos. 1 and 2 mines in the Irwin gas coal basin in Westmoreland County, and Jerome Nos. 1 and 2 mines at Jerome, Somerset County, succeeding S. Snyder, who was appointed mine inspector for the same company to succeed Arthur Young, who was recently appointed superintendent of the newly acquired Orient mine.

A. R. Budd, formerly vice-president of the Diamond Coal & Coke Co., has been appointed vice-president of the Hillman Coal & Coke Co., and J. D. Martin has resigned as chief engineer of that company to become general superintendent of the Virginia Iron, Coal & Coke Co., Inc., of Roanoke, Va.

Mike Viscosky, Alfred Ramsell, Mike Kulchek, Clement Acitelli and John Laputka, of Jerome, who were found guilty in the Somerset County Court last September of dynamiting the steel bridge at Jerome, causing a loss of \$100,000, were taken into court on Jan. 26, and given the following sentences: Viscosky, Ramsell, and Kulchek, \$1,000 fine each and costs and to serve not less than five nor more than ten years each in the Western Penitentiary at Pittsburgh; Acitelli and Laputka were each sentenced to pay fines of \$1,000 and costs and serve not less than one year and six months nor more than three years in the same institution. Upon an appeal to the Supreme Court, the former three were released on \$5,000 bail and the latter two on bonds of \$2,500.

A state charter has been issued to the Crane Coal Co., Philadelphia, the purpose of which is the mining of coal and the manufacture of coke. The capital stock is \$50,000 and the incorporators are A. B. Crane, Wayne, treasurer; J. Albert Bayley, Laurel Springs, N. J., and Joseph W. Henderson, Chestnut Hill, Philadelphia.

Mayor John Durkan of Scranton has abandoned his willingness to agree to a valuation of \$380 per foot acre on local coal lands, after he had first announced an assessment of \$800 per foot acre, through the failure of the coal companies to agree to the increase over the present \$320 value. As a result, the Mayor has announced that the board of assessors will prepare the 1924 valuation books with the \$800 figure as a basis. This is taken to mean that the appeal of the corporations will be carried into court and a strenuous fight will be made against the increase. The companies, it is understood, were willing to agree to the mayor's offer to make \$380 the valuation for this year, but wanted the provision that they could file an appeal which would stand for some time. Whether or not the compromise negotiations were broken on this point could not be learned.

Thomas W. Harris, of Taylor, was awarded a gold prize of \$250 for having prepared the best paper among a number of competitors on "Working at the Face." The presentation was made at a banquet, at Minooka, Jan. 26, tendered by officials of the Hudson Coal Co. to the employees of the Greenwich mines.

The annual report of the State Employment Bureau of the Pennsylvania Department of Labor and Industry shows that during 1923 4,524 persons applied for work in or about the mines to the various branch

offices of the bureau. Of this total 3,372 were sent to positions and 3,335 of these received work.

A charter was issued to the Windber-Coalport Coal Co., Windber, with a capital of \$60,000. The incorporators are J. Wade Snyder, Windber, treasurer; Sylvester Lehman, Windber, and J. E. Reese, Scalp Level. The company will engage in mining coal and the manufacture of coke and by-products.

VIRGINIA

The Pardee interests, owning the Blackwood Coal & Coke Co., are beginning a development project in southwest Virginia which will involve an expenditure of approximately \$8,500,000 and which when mining operations meet normal production will afford about 2,500,000 tons a year. The company will first develop its holdings on the Southern Ry. between Appalachia and St. Charles, the new mining town to be known as Calvin, for the late Calvin Pardee, who was head of the Pardee interests. A contract has been let for the construction of 300 houses for miners at Calvin. Other buildings include a club house, bath house, theatre, two churches and modern tipples. The sum of \$3,000,000 has been appropriated for the construction of the new mining plant at Calvin, which is to be the first of three. Work on the second operation will be undertaken after the plant at Calvin is completed.

WEST VIRGINIA

Captain Bob Smith of the Litz Smith Co., of Huntington, announces that his concern will open sales offices in Detroit with A. Meters in charge. A. Alexander, who has been associated with Manager Albrink of the Fuel Forwarding Exchange at Russell, joined the Huntington forces.

Under a reorganization of the Tierney Mining Co. and the Tierney Coal Co., interests of Colonel Z. T. Vinson and of Donald Clark, of Huntington, in both companies have been acquired by the estate of the late Laurence E. Tierney. Under the plan of reorganization the name of the Tierney Coal Co. has been changed to the Laurence E. Tierney Land Co., with offices in Bluefield. This company controls about 10,000 acres of coal land in Pike County, Ky., part of which is under lease. Officers of the company, just elected, are as follows: Mrs. Laurence E. Tierney, president; John L. Tierney, vice-president; Dr. L. H. Clark, secretary. Directors of the company include Mrs. Laurence E. Tierney, Laurence E. Tierney, Jr., Dr. L. H. Clark, John L. Tierney and G. C. Wood.

J. W. Knowlton, of Elkins, who has been engineer of tests of the West Virginia Coal & Coke Co. and who recently accepted the position of manager of the coal department of the Southern Power Co., left late in January for his new post at Charlotte, N. C.

Clarksburg capitalists have organized the Dry Fork Sewell Coal Co., with stock of no par value, 25 shares having been subscribed at \$500. This company will have its office at Clarksburg. Identified with the new concern are R. H. Pallerson, E. Ray Burnside, L. J. Shanan, J. M. Carter, G. M. Barnes, all of Clarksburg.

Statistics have just been made public by the Consolidation Coal Co. showing that that company and its predecessors have produced a total of 233,001,657 tons of coal in the 59 years in which they have been operating. The company mined its first ton of coal in 1864 and by 1871 a half-million tons had been produced. The Watson family has been interested in all the predecessors of the Consolidation just as they are in the Consolidation. The company's year of largest production was in 1915, 11,722,344 tons being mined in that year. In 1913 a total of 11,154,897 tons was mined.

Announcement has been made that the trial of William Blizard on a charge of murder will be the first case to be brought before the court when the "armed march" cases of Blizard and his fellow mine-union officials, C. Frank Keeney and Fred Mooney, come up at Fayetteville Feb. 11. The charges are all in indictments found in Logan County and removed by changes of venue first to Jefferson, then to Morgan, and then to Greenbrier County. The transfer to Fayette County came after a jury had disagreed in trial of Blizard on the murder charge, connected with the killing of Deputy Sheriff John Gore of

Logan during the 1921 march, and after charges had been made of attempts to corrupt prospective jurors in Greenbrier County.

WASHINGTON, D. C.

Appointments to the executive committee of the National Coal Association made at the recent meeting of the board of directors are as follows: J. C. Brydon, (Chairman), president Quemahoning Creek Coal Co., Baltimore, Md.; J. G. Bradley, president, Elk River Coal & Lumber Co., Dundon, W. Va.; Ira Clemens, president, Clemens Coal Co., Pittsburg, Kan.; E. L. Douglass, vice-president, First Creek Mining Co., Cincinnati, Ohio; Michael Gallagher, general manager, M. A. Hanna Co., Cleveland, Ohio; G. M. Gillette, manager, Consolidation Coal Co., Frostburg, Md.; T. W. Guthrie, president, Hillman Coal & Coke Co., Pittsburgh, Pa.; S. Pemberton Hutchinson, president, Westmoreland Coal Co., Philadelphia, Pa.; A. M. Ogle, president, Vandalia Coal Co., Terre Haute, Ind.; P. H. Penna, secretary, Indiana Bituminous Coal Operators Association, Terre Haute, Ind.; S. L. Yerkes, vice-president, Grider Coal Sales Agency, Birmingham, Ala.

David L. Wing announces the removal to the Transportation Building, 17th and H Streets, N. W., of his office for consultant work on industrial economics and statistics; for research work both in the United States and in foreign countries, especially Latin-American; for the conduct of inquiries and the preparation of briefs of fact and reports for submission to congressional committees, and to federal, state and local commissions and boards, and for use in litigation.

John H. Libby and Thomas K. Meloy have formed a partnership under the name of Libby & Meloy, industrial counsel, with offices in the Southern Building, Washington, D. C., and a branch office at 61 Broadway, New York City. The firm will make investigations of various phases of industry involving economics and engineering.

CANADA

A wage conference at Sydney, N. S., between representatives of the Dominion Coal Co. and officials of the United Mine Workers adjourned on Jan. 29 until Feb. 5 and issued the following official statement: "The representatives of the Dominion Coal Co. offered to renew the wage contract at the 1923 rates. Representatives of the United Mine Workers offered to renew the contract with an increase upon the 1923 rates of 55c per day for day paid workers and an increase of 20 per cent on contract-rates. The adjournment moved by the representatives of the United Mine Workers was agreed to in the hope that when negotiations were resumed, better progress might be made."

A summary of the coal trade of Canada for 1923 issued by the Dominion Bureau of Statistics shows imports of anthracite to the amount of 5,165,382 tons, valued at \$46,457,902, as compared with 2,705,752 tons, of the value of \$23,795,743, for 1922. Bituminous coal was imported to the amount of 15,822,240 tons, of the value of \$49,899,099, as compared with 10,317,773 tons of the value of \$37,387,285 during the preceding year. Imports of coke were 733,604 tons, value \$5,790,771 as against 336,270 tons, value \$3,094,042 in 1922. Exports of coal from Canada amounted to 1,654,706 tons, value \$10,661,399, as against 1,818,582 tons, value \$11,159,060 in 1922.

Industrial Notes

A. B. Day, who founded the Sanford-Day Iron Works, has organized the Day-Evans Iron Works at Knoxville, Tenn., with a capital of \$200,000. A. W. Evans, engineer of the company, who is in charge of construction work, expects to have rail connection with the L. & N. and Southern rys. soon. The new company will manufacture mine cars and general mine equipment.

The Ohio Brass Co. recently purchased approximately five acres of land, and buildings just across the Pennsylvania R.R. tracks from its present Mansfield plant. The tract is triangular in shape and is bounded by three trunk-line railroads—the Pennsylvania, Erie and Baltimore & Ohio. The purchase was made from the Aultman-Taylor Machinery Co.

New Equipment

Safety Powder Flask

Every mine owner and the workers in his mines know of the ever-present danger of powder explosions due to what have seemed unavoidable accidents with the old powder flasks. Loss of life and money is the usual result when the powder burns. It is claimed that the new Fannon's "Safety-First" Powder Flask, manufactured by the American Safety Mine Appliances Co., of Knoxville, Tenn., gives absolute control of the explosive powder. The illustration herewith shows how every possibility of accident is done away with.

A few of the safety features of the

Flask for Blasting Powder

The design of this container prevents spillage and should at the same time permit easy filling with little danger.

new powder flask aside from the hand-gripped trigger are that it prevents spilling of powder in making cartridges, prevents miners from sticking picks into kegs, and is safe from fire by bystanders—sparks or flames cannot enter the flask.

High-Speed Flexible Coupling

Couplings operated at speeds between 3,000 and 9,000 r.p.m. need to be made of steel and should at the same time provide for easy endwise movement. For these conditions the Smith & Serrell Co., of Newark, N. J., has developed a high-speed flexible coupling suitable for from 6½ to 98 hp. per hundred revolutions. This coupling is very easily accessible for inspection and for repair without moving either of the connected machines. It is of the laminated spring construction which provides flexibility and durability. As far as possible all parts are made interchangeable.

In the outer member of the coupling are keepers into which the laminated springs fit. These keepers can slide endwise; thus the bearing between the bundle of springs and the keepers is

Flexible Coupling for Turbine Drives

A high-speed steel coupling with flexible radially mounted spring bundles set so as to quickly adjust the two coupling members when driven at high speeds.

constantly upon a surface bearing rather than line or point contact. The bundle of springs also can slide in a vertical direction, making the coupling flexible in all directions.

New Model Air Hoist

More powerful air hoists of the Little Tugger type are now being manufactured by the Ingersoll-Rand Co., of 11 Broadway, New York. They were developed and perfected to meet the demand for a more powerful single-drum hoist than the 1H and 5H types.

Besides having increased power and durability, the manufacturers claim a

Air Hoist for Mining Service

much greater air efficiency than heretofore known in a machine of this type. This low air consumption is due to the fact that the motor runs in one direction only and has a specially designed piston. The air consumption per delivered horsepower varies from 25 to 30 cu.ft. per minute over a range from 5 to 11 hp. at air pressures running from 50

to 80 lb. per square inch at the throttle.

The new hoists, known as the 10H class are made in three types, each type specially suited for its particular field of operation.

The slushing hoist has deep-flared flanges which serve to eliminate rope and drum wear when the rope is not led on straight. The general-purpose hoist differs from the slushing only in the provision of a drum with straight flanges and the addition of a brake band and other brake details. The 10HL, or large-drum, hoist differs from the general-purpose hoist only in size of drum and base. This hoist is intended for work where a large drum and exceptional rope capacity are needed.

Heavier Designed Section Insulator Switch

A heavier design for all the needs of modern heavy electric haulage—greater current capacity, ruggedness, and mechanical strength for withstanding constant passage of high current locomotives—and a method of suspension which simplifies the problem of roof clearance are features of a new Ohio Brass Co. section insulator switch.

Like other O-B section switches this new design provides an underrun for the trolley wheel, even though the switch itself may be open. This is provided for in the rigid underrun across the circuit-breaking section of the switch. All parts of the switch are heavy for severe service with heavy locomotives and heavy motor currents. The approaches, the underrun and the knife-blade circuit breaker and clips are designed for a heavier than ordinary rating, ample for all requirements—even to carrying the feeder line through the switch. Lugs on each end of the switch permit installation of feeder connections and allow for opening the feeder circuit as well as the trolley circuit when the switch is opened. The switch is designed for 4-0 trolley wire and will take feeder wire up to 4-0.

The two suspension brackets are set so that the hanger support is below the top of the switch. Thus it is possible to keep the trolley height even with one of these switches without cutting into the roof for clearance. Standard insulated hangers should be used with a section insulator switch, for by this scheme of support they may be used without serious problems of clearance. Hangers are installed just as they would be for trolley clamps, and the switch is attached without further roof drilling or chipping.

Section Insulator Switch of Heavy Construction

This new switch is capable of carrying heavy feeder line currents into any section of the mine, thus making possible the combination of trolley and feeder switch in one.

NEW YORK, FEBRUARY 14, 1914

Number 7

For a New Era in Safety

SAFETY in mining has been endowed by the accident compensation acts. Prevention of accidents has been made profitable and can no longer be regarded as an unremunerative, though worthy, way of spending money. Unfortunately, the effect of compensation has not been as great as might have been expected. Several ways of obtaining greater safety still are being overlooked, and it seems now, after several years of accident compensation, that the laws must be strengthened.

In many sections of the country have been found operators ready to co-operate in a revision of the laws having that end in view. A. J. Moorshead tried through the American Mining Congress to have such revision put into practice, but his effort seems long ago to have spent its force.

The Rocky Mountain coal operators are actively advocating better legislation and the Rocky Mountain Coal Mining Institute is even now canvassing ways of achieving greater safety in the dry areas of the West. This effort of the operating men will surely meet with the approbation of all the mining fraternity.

Some time back some of the western Pennsylvania operators sought to eliminate the menace of mixed lights by demanding that all mines having areas operated by safety lamps be operated entirely with such lamps. They were not successful, however, in procuring sufficient support to make their legislative plans successful.

An effort should be made to get safety measures required in one state adopted in all others where conditions are similar. Much credit should be given to those concerns which, like the Old Ben Coal Corporation, have adopted safeguards outdistancing those provided in mines confronted with similar safety problems. In the long run such precautions are not only salutary but profitable, especially when taken to prevent such accidents as may involve a whole mine in a common catastrophe.

A New Use of Trade Associations

A SPEAKER at a recent meeting of the Philadelphia Coal Club jocularly refused to give statistics regarding farming, for fear that agents of the Department of Justice might be around. We must be equally careful and shall avoid giving any statistics of mine explosions caused by coal dust, for fear some one might make an improper use of them.

A brick, we are told, is a construction material of use in masonry, but it has been used to commit murder. Statistics resemble that brick and if someone used it improperly, the Department of Justice might ask who it was that smuggled in the brick and we could be convicted of being the guilty party. Someone might say, for instance, that mine explosions were so many and the cost is so high that the price—but that is enough.

Before we write more we must ask the subscription department if Secretary Daugherty or any of his henchmen are reading *Coal Age*.

Avoiding bricks, whether in hand or in flight, we wish to suggest a new use of trade associations. Could not some such body erect for its members a mill, centrally located, yet far enough from the mines to avoid having a scale made for it by the United Mine Workers, where rock could be ground for the use of members and others in the rock dusting of mines? Of course unless it was intrastate it would not be allowed to ascertain the cost of the installation, the cost of grinding the rock, the quantity ground or distributed, the percentage of its product that would go through any given screen, but nevertheless it might be well to install it if it could be done without the aid of statistics and if it rendered no accounts to its members. At least, we believe it might be permitted to exist for a while till the Department of Justice tried once again to legislate the action into one of criminal intent.

Such a mill could do much to make mines safe in the area it served. The suggestion has been made to *Coal Age*; it surely is worthy of consideration—if legal, of course.

Can't Win with Poor Cards

NO ONE can hope to meet the present low cost of coal with equipment that has a high cost of operation. Circumspect development is the one hope for staying in the competition. If care be taken to provide appliances that will save labor and increase production the race may be won. Mere economy and a decision to get along with what equipment is in hand may carry a plant along a month or so, but only judicious expenditure will give the operator such advantage as to protect him for a long period of low prices.

Coal operators in flush times overextend themselves. They load their financial structure with mines and lands until it fairly groans under the strain. They do not put enough of their profits back into the plants they have, but squander their money in plants they desire to add to their holdings. As a result when the close margin comes they are taken entirely by surprise.

If they had loading machines and shortwall cutters, good tracks and switches, pipes and screens which did not have to be perpetually renewed, automatic substations, reclosing circuit breakers, pumps and doors—to mention a few items—they could clip off the few cents that would keep them out of the market, and, being in the market, they would be able to run steadily and clip off some more cents.

A vicious cycle in high cost perpetually drives the operator further and further to the wall. When the cost is high, the price of coal must be high, and being high must be made a little higher because the mines cannot run steadily. When for this reason the price

is raised a little higher, then the mine runs still more irregularly, and the price must be raised again. Just a little advantage—two cents on the steady-run basis—may make a difference of ten or more times that much because of its effect on steadiness and intensity of run.

Times of low prices call for high courage combined with circumspection. A little diligent figuring, however, will show just where a man can be relieved here, there and the other place to engage at other and more profitable work for the company.

There are in this world but two cycles, the cycle of success and the cycle of failure. A little profit makes efficient operation and steady business and spells success. A little loss of money and of faith results in an excessive economy and that again in inefficient, irregular, ill-sustained operation and bankruptcy. A trifling difference in cost oftentimes separates the two. Low cost sets the cycle of success in operation. High cost brings in operation the vicious cycle of failure.

Give Them a Boost

YEARs of experience have given the coal industry confidence in the U. S. Bureau of Mines. It is critical of the industry but not muckraking. It holds up a true mirror to us and to the public. We see ourselves not as others see us but as we are. They "nothing extenuate nor set down aught in malice." For a little while the Bureau seemed to be following the lines of government organizations which prescribe "Make out a bad case against industry, and jobs, salaries, honor and public approbation will flow therefrom." The Bureau has come scot-free from that Adam's apple, tantalizingly tempting as it was. It never tried to tell anything but the truth, and the best elements in the coal industry have been helped. As for the worst, no one wants to spare them. They are the true enemies of every coal man, vociferously though they may declare their interest in backing the industry.

Manning, Cottrell and Bain have each in their turn tried to do their work fearlessly and constructively. Mistakes of judgment may have been made but not of heart. They have deserved a more outspoken note of approval. Their effort to keep safety before the industry should be given wholehearted support. Their advocacy of rock dust should bear more effective fruit. Their investigations of safety appliances should meet with greater interest and what they have recommended and devised should have speedier acceptance.

They are the friends of the industry and no one can conceive any instrumentality better suited than the U. S. Bureau of Mines for the obtaining of that greatest of needs for the reformation of the industry—cleaner coal.

A concern in Buenos Aires purchased its coal for some twenty years from a company of standing in the United States. In the course of those years the mine became exhausted, and the Argentine firm was notified by the American company of that fact. "We have," said the United States company, "other coal which might suit you." The Argentine firm tried it and did not like it as well. Its officials, accordingly, said: "There are lots of mines in the United States; let us try some of them." They did so, and got in the hands of the sharks that seem more active in the export field than perhaps in the domestic. As a result these Buenos Aires buyers said they would never try again to buy in this country. They purchased coal from Europe and told an American

commercial attaché that never till the United States would guarantee coal quality would they again be in the market for coal from this country's mines.

Shall we never learn that adequate inspection has been, and ever will be, the sheet anchor of successful trade?

Better Inspectional Forces

RECENT explosions and the high death rate in the mines of the United States make it essential to improve the inspectional service. At present we have no adequate safety organization. In each state we have only chief inspectors and subalterns. The latter have a hard life traveling through the mines and being always away from home. Their salaries are small. Though their tenure of office is reasonably secure and in most cases not threatened by politics, they have no hope of promotion. Increased comfort, decreased exertion with advancing years, growing public appreciation are denied them. Such conditions do not provide the best men. The inspectional service is a blind alley.

In Great Britain, on the other hand, there are grades of inspectors. The upper classes of the service are spared the drudgeries of general inspection. When a problem is presented they act to settle it, and being more competent than the general run of the inspectorate and living on a higher plane of social recognition they are able to approach those who wish to contravene their authority or stretch the law by some technicality with a degree of confidence and understanding that makes their representations respected. It is difficult for a \$4,000 or \$5,000 man to make the \$25,000 or \$50,000 president of a large company realize that he must conform to some practice which safety prescribes or the law requires.

Furthermore, our inspectors in general have not received technical training. They have experience obtained in actual contact with mining problems. They have studied enough to obtain a certificate but most of them know little enough about electricity and almost nothing about the other forms of safety that would throw light on safety at mines. They are rarely traveled men. They know their district well and they know perhaps more than their district knows but there is no incentive to acquire more. They are safe to continue to be inspectors without this further instruction. The safety services of the coal mines are better than we have any right to expect under present conditions, but why not take the steps that will make them still better?

MR. LEWIS' IDEA of the proper place for the wage scale negotiations, concurred in by a few operators, was an unfortunate one from many standpoints. The choice of Jacksonville, Fla., for the Feb. 11 conference too easily gives the impression that operators and miners are entering the forthcoming parley in a playful, vacation mood. The argument that the negotiations ought to be removed as far as possible from the interfering influences of the coal states is thin soup. If the sessions should be drawn out at great length the unpleasant impression of the conference would be intensified over the country. Hence it will be good policy for both sides to knuckle down to business at once upon their arrival in sunny Florida and do the one logical thing without delay—extend the present wage agreement.

Three Methods of Preparation And Two of Shipment Embodied In Design of Indiana Tipple

One Grizzly and Two Shaking Screens Used—Five Sizes May Be Shipped by Truck, Eleven Sizes by Rail—Large Concrete Storage Bins Facilitate Local Shipments and Relieve Car Shortage

A NEW four-track steel tipple recently was completed by the Clinton Coal Co. at its No. 2 Crown Hill Mine located near Clinton, Ind. This improvement has been made at the shaft where two years ago a 1,500-ton rescreening and wagon-sales storage bin was constructed. The combined equipment makes coal preparation at this mine unusually complete. The plant as a whole is the result of the determination of the owners to be ready to meet a recurrence of every market and operating contingency that has arisen in the past as well as those which business experience indicates may be expected in the future.

Three methods of preparing coal are provided in this plant. The first is the preparation of run-of-mine over a 1½-in. bar screen, making standard 1½-in. lump and 1½-in. screenings. This product can be made without operation of any mechanical screening equipment and is intended to satisfy that portion of the trade that has become accustomed to this kind of coal, having used it for years, and which therefore still demands it.

ALL LARGE COAL LOADED OVER BOOMS

Passing the coal over a horizontal screen, where it can be picked, and then loading it into cars on four tracks forms the second method of coal preparation. The three larger sizes are loaded over loading booms. Screening in this manner together with provision for picking and for loading into cars by means of booms

is all that is necessary in order to obtain the best domestic preparation.

The third system of handling coal at this plant consists of delivering the run-of-mine from the weigh hopper in the tipple direct to an elevator, by which it is raised and then screened over a horizontal screen into five sizes, each of which is deposited in a separate concrete bin. The sizes made are designated as screenings, pea, nut, egg and lump coal. The bins are quite wide and each is fitted with two openings, or gates, in the bottom. One of these gates delivers to cars on the screenings track under the tipple. Thus all coal prepared in this manner can be shipped by rail if desired. On the other side of the bins the coal is loaded directly into wagons. A mechanical rescreen is inserted in the wagon chutes, which results in an extremely high-grade coal being available to the town of Clinton, located at a distance of a mile and a half from this mine.

The space below the bins is provided with a concrete floor or pavement. This is extended so as to make connection with a concrete road leading to Clinton. The capacity of the bins is such as to provide for a large wagon and truck business. It also serves for coal storage frequently relieving the situation when there is a car shortage and these sizes are being shipped.

FROM CAGE COAL MAY TAKE SEVERAL ROUTES

A brief description of the method of handling and the mechanical equipment follows: The coal is discharged from self-dumping cages into steel chutes which deliver it to a bottom-door gravity-dump weigh hopper serving a chute and bar screen. In case bar-

Excellent facilities for wagon shipment are provided at few mines. The headpiece shows how the Clinton Coal Co. has made provision for local delivery. The concrete bins here shown span not only one railroad track but a paved wagon space as well. Shipment of any size may thus be made by either car or truck.

Fig. 1—Side View of Tipple

In addition to the four sizes made over the tippel screens, two sizes made by a bar screen, as well as run-of-mine, may also be shipped.

screen coal is to be sold the veils covering this screen are lifted and the screenings delivered direct to a hopper above the slack track. The 1½-in. lump coal flows to a feeder hopper which delivers to an apron loading boom over the nut-coal track.

In case run-of-mine is to be loaded the veils over the bar screen are closed and the entire mine product is loaded over the boom on the nut track. The reciprocating feeder is so adjusted that it delivers the coal to the boom quickly, so that an interval is preserved between dumps from the mine car. Thus this boom can be used for inspecting the contents of each car for docking purposes.

BYPASS SHUNTS THE COAL TO THE BINS

When it is desired to send coal to the concrete bins for preparation a door below the bar screen is opened and the run-of-mine delivered through it to an apron conveyor. This in turn feeds a gravity discharge elevator which delivers the coal at the top to a horizontal screen 5 ft. wide. This screen is provided with

¾-, 1½-, 2½- and 4-in. openings. The larger sizes of coal are picked at intervals along this screen and the refuse deposited in the rock trough, which delivers it to a small bin at the end of the storage bins, whence it is hauled away in wagons.

If it is desired to prepare the coal over the screen in the tippel another door in the chute is opened. This deflects the coal to the reciprocating feeder directly below it, which in turn distributes it evenly on a 6-ft. horizontal screen. This separates the coal into 1½-in., 3-in., 6-in. and lump sizes, thus making grades that are standard in Illinois and Indiana. The larger sizes of coal can be picked on this screen. The pickings are placed in the refuse trough over the screen and delivered beyond the lump track into a bin from which they are hauled away in wagons.

ROCK IS READILY SENT TO WASTE

Another feature of interest embodied in this installation is the means employed in handling rock from the mine. Doors are placed in the dump chute above the weigh hopper. These, when opened, deliver rock to a steel bin at the side of the tippel. A side-dump car draws rock from this bin and proceeds up a 10-deg. incline to the gob pile beyond the railroad tracks. This incline extends directly over the three loading booms and is in the same position that it occupied before the steel tippel was built, its trestle having been incorporated into the new tippel structure.

The provision of three distinct methods for preparing the coal is the most unusual feature this preparation plant embodies. In a measure it is exceptional also in the excellent facilities that have been provided for shipping the entire mine output or any portion of it in prepared sizes for local consumption.

At this plant the rescreen and storage bins were built by the coal company while the equipment and machinery was furnished by the Roberts & Schaefer Co., of Chicago. The steel tippel also, including all equipment, was designed and built by this same firm, actual erection being performed by R. G. Lawry, contracting engineer.

FIG. 2

Local Bins

This picture shows the concrete bins extending at right angles to the tippel proper, in which are stored five sizes of coal that are prepared on screens above them. From these bins the coal may be delivered either to trucks or wagons located in the paved space below them or to railroad cars on the slack track. Coal for local delivery is rescreened making an exceptionally good product.

Building a Long Retarding-Conveyor Gallery at Brotherhood Mine, Coal River Collieries

Structure Rises 800 Ft., Is in Places 40 Ft. Above Ground and 1,400 Ft. Long, the Maximum Grade Being 35 Deg.—How Joints Are Stiffened and Strengthened

BY W. J. DENMAN

Assistant Engineer, Coal River Collieries

LONG rope-and-button coal retarders often must be provided with trestles of considerable height and must be erected on such pitches as to bring heavy strains on these structures. When these trestles are built of wood, shrinkage occurs, weakening the joints on which so much depends. Care therefore should be taken to see that the bolts are kept tight at all times lest the structure become loose jointed and crowd down the hill onto the tippie below. The height of the building is not merely to be measured from some point on the hill to the peak of the roof immediately above it but from the bottom of the bin on the top of the hill down to the railroad track. This great height makes the trestle inherently somewhat unstable. It is necessary therefore that it be held rigidly together.

At the Brotherhood mine of the Coal River Collieries, on the Laurel Fork of Big Coal River, Boone County, West Virginia, has been built a headhouse and conveyor gallery of somewhat unusual construction. The new headhouse is located 1,400 ft. away from the railroad and some 800 ft. above it, the coal being conveyed to the

tippie at the railroad by a rope-and-button conveyor (one of the longest, if not actually the longest, ever installed in a single unit). The maximum slope of the conveyor is 35 deg. The headhouse bents in general are built of 10x10-in. timber with 2x8-in. bracing and with all intersections bolted. On the conveyor gallery the bents range from 5 to 40 ft. in height with standard 8x8-in. and 10x10-in. four-post tower construction having 2x8-in. level and cross bracings, all intersections being bolted. With such a structure we expected to have much expense for upkeep and inspection. The joint bolts would have to be tightened continually, that being our experience with bolted structures.

USE PLATES TO STIFFEN TIMBER JOINTS

In order to avoid some of this uncertainty and expense and to make a structure unusually stiff and safe we used a new device consisting of a cold-rolled steel plate of special composition which is made in square and round forms. The dimensions of the square plates are 1½ in., 4 in. and 5 in. The round type has a diameter of 3 in. A hole in the center of each plate is made of ample size to permit the passage of the bolt with which it is used. The edges of the plate are cut so as to form triangular teeth ¾ in. high and about ½ in. wide at the base. These teeth are turned alternately up and down so that they project on both sides of the plate. They are so designed that when the plates are inserted in the timber joints they relieve the bolts of most of the shear stresses.

In Fig. 2 is shown a view of one of the timber-joint plates, clearly illustrating their construction. These plates can be used in bolted and in other forms of timber joints such as post joints, eliminating thereby the necessity of a pin and mortice. Our first use of them, however, was in connection with bolted work. They were placed between the members of a joint so that the bolts passed through the two members and also through the hole in the center of the plate. The entire joint then was pulled tight, causing the teeth to bite into the wood on both sides of the plate.

When we first considered these timber-joint plates our main desire was to obtain a more rigid structure with a greater factor of safety. Tests made by the Department of Civil Engineering of Columbia University at its testing laboratories showed the results tabulated in Fig. 3. They were made on a number of

Fig. 1—Rope-and-Button Conveyor Gallery

This longitudinal cross-section shows a half span between two bents, the joints being stiffened by specially designed plates and the spans by an inverted truss.

joints each made up of 4x5.93-in. yellow-pine timber, with two 2.02x5.93-in. yellow-pine splice plates, three $\frac{3}{4}$ x10-in. bolts, six $\frac{3}{4}$ x3 $\frac{1}{2}$ -in. washers and four 4x4x0.052-in. timber-joint plates, the bolt holes being of 1 in. diameter and the plates being countersunk in the splice and main members. In the first test the plates were squeezed into the timbers by pressure applied to the top and bottom of the splice plates by means of a testing machine. The other two joints were simply tightened by the $\frac{3}{4}$ -in. bolts. The three joints were subjected to tension through suitable connections attached to the main and splice timbers and the relative movement of splice plate and main members was measured with an extensometer.

WHEN JOINT IS WELL MADE TIMBER IS SAVED

Because these tests demonstrated that a joint made up with these plates was much stronger than one made up merely with bolts we were able to effect radical savings in the materials and labor required for the work.

The illustration in the headpiece shows the conveyor gallery near the foot of the hill and indicates the type of construction used when the bents required were long. Fig. 1 gives details of the conveyor-gallery bents and indicates how the plates were installed. Four-inch plates were used throughout.

Similar plates were used in connection with the 2x8-in. bracing in the conveyor gallery, making a more rigid job and eliminating one-half the number of bolts which otherwise we would have had to use.

Four-inch plates were used where the 10x10-in. posts of the high tower bents were lap-spliced, a single,

Fig. 2—Bent and Cross-Section of Gallery

In the upper right-hand corner is one of the special plates and on the right a scarf joint stiffened by four of these devices.

Fig. 3—Tensile Test of Timber Joints with Special Shear-Sustaining Plates

The curves of deformation have each an individual baseline marked "0." Pressing the plates into the timber apparently makes little difference under a tension of 11 tons but allows seriously greater deformation thereafter.

instead of a staggered, line of bolts being used. Despite the reduction in material and complexity, greater stiffness and strength was obtained than could have been afforded by joints of the original design.

Fig. 1 shows the details on the conveyor gallery on the upper part of the hill. It will be noted that timber-joint plates have been used in splicing 6-in. x 10-in. x 40-ft. built-up beams. These beams were built of two lines of 2x10-in. oak planks, 18 ft. and 22 ft. long, respectively, with filler splices at the ends and centers 8 ft. in length. Plates were used at these splice joints.

To the present our experience has been exceedingly satisfactory and we hope, as is claimed, that even where the timber dries out, the rigidity of the joint will not be impaired. So far, we have not had an opportunity to check up this in detail, but though the wood has already dried out somewhat the joints do not show the slightest tendency to loosen, nor was there any splitting at the bolt holes. On the contrary, the plate seemed rather to prevent this action from occurring. Periodical inspections, however, are still being made.

So far we have used these plates only where they can be held by the compression of bolts. In the approach trestle to our No. 4 tippie we expect to install them on the tops of the caps and under the stringers, eliminating dapping and doweling and keeping the timber faces apart, thus decreasing rot and increasing the life of the timber.

Useful Data on Storage Batteries For Non-Technical Men

"Elements of Storage Batteries," by Jansky and Wood, describes in a clear and simple way the principles, operation and maintenance of storage batteries for the non-technical man who is desirous of getting the highest efficiency out of the batteries which he uses or supervises. The underlying principles of the various types of storage batteries are explained in considerable detail. An important section of the book is devoted to the proper charging of the batteries, together with a description of various types of charging equipment. The book is published by the McGraw-Hill Book Co., 370 Seventh Ave., New York.

Specially Designed Motors for Larry-Car Service

Mechanical Details Are Such as to Accommodate Heavie Axles—Must Have Armature Winding and Gear Ratio Suitable for Slow Speed—Motors Fitted with Ball Bearings

BY C. A. ATWELL

Motor Engineering Department
Westinghouse Electric & Mfg. Co.

ELECTRICALLY driven larry cars have lately come into more general use around the mines as coal transfer cars, slate dumping cars, scale cars, concentrator cars and for many other uses about docks, quarries, steel mills, coke plants and other similar industries. While their uses and types of construction are numerous, they all have the common features of being self-propelled, burden-bearing cars and usually operate at speeds that are low compared to electric railway service.

The motors used for propelling larry cars should be of the same general construction as the modern railway types of motor; that is, they should be series-wound, commutating pole motors of rugged construction suitable for mounting on the car axle and geared to the axle by single reduction gearing. The features that were mentioned above as common to all larry cars place several special requirements on the motors, however, that are not required for the usual railway motors. This makes it necessary that the motors which are entirely suitable for use on larry cars be designed especially for that service. The principal special requirements are:

- (1) Extra large axle bearings.
- (2) Slow-speed winding.
- (3) Ball-type armature bearings.

The fact that larry cars are built primarily for carrying heavy loads necessitates a truck design using a large axle. This in turn requires larger axle bearings than are customary for the usual railway type motor

Fig. 1—Outline of Larry-Car Motor

Much depends upon the axle diameter, D , because if it is increased the gear center distance, A , increases and C , the clearance under the gear case, increases because of the use of a larger gear. B is the clearance under the motor frame.

The headpiece shows a typical mine larry car. The use of this car is rapidly increasing, due to the larger capacity and the ease of dumping. The arrangement for dumping usually is made to fit the conditions far better than is possible with the ordinary mine car.

Fig. 2—Larry-Car Motor

This specially designed motor is rated at 80 hp. and 230 or 550 volts. The axle bearings are for an 8-in. rear axle. Ball armature bearings permit higher motor efficiency and proper lubrication of the bearings without overflow into the motor and windings.

of the same size such as are used on street railway, interurban, or even freight locomotive service. In Fig. 1, the dimension "A" represents the "gear center distance." On standard railway motors this distance usually is made a minimum for the largest size axle that is likely to be used with a certain motor. A minimum distance, "A," has the advantage of a maximum clearance, "C," between the gear case and top of rail. In order to increase the axle bearing bore, "D," the gear center distance, "A," must be increased. A gear with more teeth is used to make up for the increase in gear center distance and mesh with the motor pinion. The clearance, "C," is reduced by the same amount that "A" is increased. As it is not necessary for "C" to be as large for slow-speed service as on high-speed railway service, this decrease is not detrimental.

The voltages common about industrial material yards where larry cars are used generally fall within the ranges of 230 to 250 volts or 500 to 550 volts. Of these voltages the most common are 230 and 550. A car speed within the limits of 8 to 12 miles per hour at the nominal rating of the motor usually is desired.

Fig. 3—Load Rating of Ball Bearing

It will be observed from this curve that the manufacturer's load rating decreases with increase in speed. This curve shows the extreme impact loads the bearing will withstand at slow speeds.

The special voltage and speed requirements of the larry car service practically prohibit the use of an existing railway motor winding. It sometimes happens that a standard high-speed 600-volt railway motor, when operated on 230 or 250 volts, will run at the desired speed; but, due to the fact that the motor is designed for 600-volt service, the ampere capacity of the copper conductors in the windings will not be adequate for the lower voltage. This will result in obtaining less horsepower for a given motor size and weight than is ob-

Fig. 4—Motor for Narrow Track Gage

This motor is rated at 7.5 hp. and is made for use on larry cars operated on 18-in. track gage.

tained from a larry car motor which has a winding designed especially for the voltage and speed required in such slow-moving equipment.

Ball armature bearings are preferred to the sleeve type on larry-car motors for the same reason as on mining locomotive motors. They require less lubrication and attention and maintain the armature in a central position with respect to the field poles. Ball bearings usually are lubricated with grease while sleeve bearings are lubricated with oil, which often results in over-oiling and a consequent entrance of oil inside the motor, where it damages the windings or commutator. Ball bearings have not been accepted as standard on the higher speed railway motors, but this is due to the mechanical inability of the ball bearing to stand up under the conditions of high armature speed and impacts received at high car speeds. The average speed of the larry car service is even lower than that of the mining locomotive, so the odds are strongly in favor of the ball type of armature bearings. Fig. 3 shows how the manufacturer's rating of a ball bearing increases as the speed decreases.

Fig. 2 illustrates an 80-hp. larry-car motor that possesses the special requirements mentioned above. The following tabulation shows comparisons of this motor with a high-speed 600-volt railway motor that has the same size of frame and same armature and field-pole dimensions.

COMPARISON OF LARRY-CAR MOTOR WITH HIGH-SPEED RAILWAY MOTOR OF THE SAME PRINCIPAL DIMENSIONS

Preventing Stray Currents from Detonating Explosives

Ground Currents Cause Premature Explosion—Potential Differences Reduced by Intercconnections and Grounds—Keep Firing Cable Well Insulated

By E. E. JONES

GROUNDING of electric equipment is highly desirable, but this alone is not sufficient because current leaks into the ground create relatively high potential differences between strata of earth and metals. Whenever liability of explosion exists from gas or blasting caps, the whole surrounding region should have little or no potential difference between objects. The blasting circuit is most important of all. It should be well insulated and free from splices or broken insulation. It should be inspected frequently—at least every day. Usually leakage of stray currents into the blasting circuit are the cause of premature explosions because the cable or conductors often span areas or materials having high potential differences.

JUST as the men employed in sinking a shaft at Stotesbury, W. Va., for the E. E. White Coal Co., were in the bucket descending to the bottom there was a premature detonation of a charge that had been previously set. The shaft was at that time 65 ft. deep and, owing to the fact that the bucket had only started down, a fatal accident was narrowly averted. Investigation showed that the explosion was caused by stray electric currents in the ground and metallic connections to a pump and hoist equipment; hence it was not safe to proceed with the work until this condition was corrected.

Some of the men refused to work in the shaft unless steam was used in place of electricity for operating the hoists and pumps. This was practically out of the question, since the electric equipment had already been installed. It was decided, therefore, to make tests to determine the cause of the explosion and to decide upon the remedy.

The system we were using for power was grounded on one side and supplied by a 1,000-kw. rotary converter,

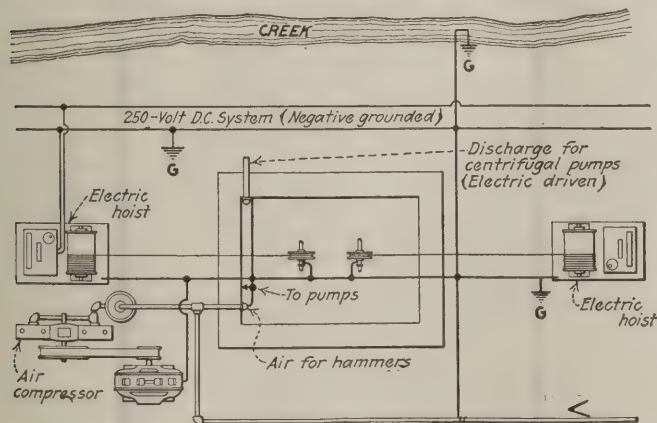

Fig. 1—How the Equipment and Pipes Were Interconnected and Grounded

The heavy lines show where a solid 0000 copper conductor was connected and grounded, thus reducing the potential difference between various objects to a point too low to set off a blasting cap.

From *Explosives Engineer*, September, 1923.

similar to those used in street railway systems except that 250 volts were employed instead of 500 to 700, as in street railways. First, all the switches in the hoist, pump, motor and compressor circuits were opened to make sure that the trouble was not caused by a leak from the positive side of the system to any of these machines.

While the switches were open, an electric blasting cap was connected between a pipe in the air line and

Fig. 2—Elevation View of Shaft Showing Ground Connections

By thus effectively grounding the system of electric apparatus, pipe lines and tower the confidence of the workmen was regained and the work made safe.

the discharge line from the pumps. The instant a connection was made, the blasting cap detonated. A connection was then made between the air line and the ground adjacent to the shaft. The cap detonated, but not instantly, which showed that there was not at all times sufficient voltage between these points to fire a cap.

Next, a connection was made between the metal of the hoist frame and the ground, and the blasting cap fired instantly. Finally, a connection was made between the bottom of the shaft and a wet place near the surface; in a few seconds the cap detonated. From these results it was evident that there was a sufficient difference of potential present in the various places selected to fire blasting caps connected in an ordinary circuit in the shaft.

To equalize the voltage at various points around the surface and at the bottom of the shaft, the frames of all the machines on the surface and the pump at the bottom of the shaft were metallically interconnected with a heavy copper conductor and grounded. The two hoists were connected by a heavy copper cable which was grounded; this cable also was connected to other surface equipment and to all pipes going down the shaft. The grounds at the two hoists were made by burying a coil of 0000 copper wire in a hole 4 in. deep. Salt water was poured on the coil to increase its earth contact. The different connections and grounds are shown in the accompanying diagrams.

After this work was completed \$25 was offered to some of the most intelligent workmen if they could fire an electric blasting cap by connecting it in any way that it would explode, without, of course, using a blasting machine or the power circuit. None of them was able to fire a cap in this way. After the tests the caps used were fired by connecting into a power line to prove that they were good caps.

Tests were then made with a mili-voltmeter, with which no difference in potential greater than 100 mili-volts could be detected between any two pipes, from any of the pipes to the ground, or from the top of the shaft to the bottom. When it was thus demonstrated that danger from stray currents had been eliminated the confidence of the men was restored.

New Coal-Cutting Machine Drives Gangways

Same Device Cuts, Breaks and Delivers Product—
Entries May Be Driven on Both
Sides of Main Gangway

BY ARTHUR GERKE
Waldenburg, Silesia, Germany

ATTEMPTS at driving galleries in a coal seam by machines date back to the time when boring by means of machines was begun. Technical periodicals and books of the last decades contain descriptions of machines which were successful only in so far as they were patented. Many were put to test, but without the result hoped for. That all these attempts failed probably is due to the fact that it was impossible to produce equipment that could stand the great strain of coal cutting, and to provide a guide that excluded any deviation from the direction intended.

In spite of these failures, however, the activity of inventors has not come to a standstill, and numerous appliances have been patented. The solution of the problem would be of special importance to the mining industry, since driving galleries means waste of money and time. The quicker the gallery advances, the sooner large-scale mining may begin and the larger will be the number of men at work. As the advantages to be gained are many, a description of a new coal-cutting machine, called "Rotatia," is of interest. Some time ago this machine was introduced in the German, Czech and Hungarian mining industry and proved a complete success.

This rotating coal-cutting machine consists of three main parts: (1) The driving device; (2) a system of tubes for lengthening; (3) the cutting device, which consists of cutters composed of several parts, and the mechanism for vertically cutting or breaking the core, likewise composed of several parts.

The driving device, fixed on a carriage, is secured on an inclined plate at any point from which a gallery is to be driven, while the cutting device is kept in close touch with the face of the coal through the system of lengthening tubes, as shown in Fig. 1. The whole system is connected with the shaft of the driving device by a special coupling. The lengthening pieces are tubes with flanges and are connected by keys and two locking screws. The cutting device is fitted to the last lengthening piece and rests on a column provided with

The following rules were strictly enforced:

(1) Explosives must be in an insulated container when lowered down the shaft. (2) No more than two men can be in the shaft while the shots are being prepared. (3) The muck bucket must not touch the bottom of the shaft during the preparations for a blast. (4) The blasting machine must be in possession of the top man and can be used only by the men who prepare the shots in the shaft and then only in the presence of the top man. (5) The shooting cable must be inspected daily from top to bottom. If a bare place is found, the cable must be thrown away and a new one obtained.

I consider No. 5 a very important rule, because if stray currents should develop, the danger would be greatly reduced if the leading and connecting wires were all well insulated. I am glad to say that no one was seriously hurt during the sinking of the shaft.

an adjustable bearing, stayed against the roof or the sides.

At a suitable distance from this column a second column, which also may be stayed and arranged in various positions, is provided with an adjustable bearing. On the cutting shaft behind this second column is mounted the cutting device, as shown in Fig. 2. The arms of the cutting device are connected by means of rings which correspond to the diameter of the cut to be made. The cutting device on the cutting shaft has on its front side a crown cutter for preliminary boring, which serves as a guide for the cutting device and also makes it easier to cut the core.

The arrangement for cutting the cores is mounted in the cutter arms. On every second arm, lying opposite each other, there are cutters of equal size and form, one set for cutting the outer, the other for cut-

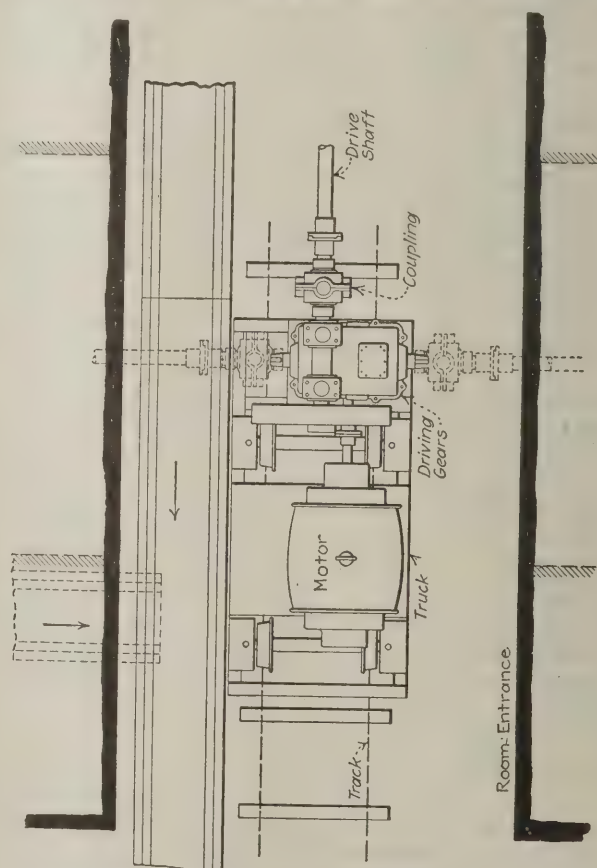

Fig. 1—Machine Which Mines Coal

This device drives a rotary coal cutter which mechanically cuts, breaks and loads coal.

Fig. 2—Cutters Projecting from Two or More Rings Are Driven by a Long Line of Shafting

What will puzzle the American reader will be to tell how the coal can be removed with a line of shafting and posts filling the roadway for a distance which in cases is said to be 230 ft. This is effected by those rocking or swinging chutes, which, introduced in Germany, Belgium and Great Britain, are now finding their way into the mines of the anthracite region of the United States. The shaft is extended as the cutters advance, new columns being erected for its support. This must cause some delay in the operations. The columns are adjusted readily by a screw with ratchets.

ting the inner core. These cutters are arranged in a circle which exactly corresponds to the diameter of the cut to be made. These core cutters are behind the arms of the rings holding the cutting tools and are regulated by springs. When the machine is in operation the driving mechanism is set in motion by compressed air or electric power. The cutting operation begins as soon as the advance work is completed, and the cutting tools begin to work, making one outer and one inner circular cut. If the coal is very solid, a third narrow cut is made near the center.

After about one foot of coal has been cut, the advance work stops and the cutting device continues rotating about its shaft without advancing. The core is then cut or broken by the operation of a special mechanism on the arms of the core cutter. This core-

cutting device consists of parts like sickles which are advanced into the coal with an up-and-down motion so as to break the outer and the inner core. The broken core falls in lumps of large and small size and these are carried off by means of a rocking or swinging chute. When the whole of the core is cut, the advance work again begins to act and the cycle of operations repeats. The advance work may be extended to the total length of 3 ft. After 3 ft. has been cut, a lengthening piece is screwed on and work proceeds. Additional lengthening pieces are added as required.

As the roadways advance new columns must be set. The system of lengthening tubes may be extended to about 230 ft. when necessary. The driving device may be shifted from the entrance into the gallery and the work carried on to any desired point.

Figs. 3 and 4—Cutting a Room in One Direction or in Two

The figure on the right shows the cutters working in two directions on a longwall face, the coal left by the cutter doubtless being removed by picks. In this case loading can be performed readily, as the track can be set alongside the drive shaft.

Frequently the rotating coal-cutting machine is employed as shown in Fig. 3. The first gallery may then be driven parallel with the main level to a length of about 230 ft. Then the adjoining part of the seam will be cut and the work continued. In case cutting devices that rotate in opposite directions are used, the mining system may be carried on as depicted in Fig. 4.

For the attendance of the machine three men are required, one driver and two cutters. In a day's work, that is, two shifts of eight hours each, an advance of about 10 to 15 ft. can be made if a diameter of 8 ft. is chosen, these figures referring to work done under usual conditions; they probably would be exceeded when the coal was not very hard.

The advantages of the Rotatia are: No blasting is needed, considerably more cutting can be done and timber costs are lower, as the roof will be more even and consequently less timber will be needed. Considering these advantages, the cost of buying and operating such a machine are of secondary importance.

Barricades Against Gas Save Lives of 275 Miners

But in 140 Disasters About 1,400 Were Killed by Afterdamp, Almost as Many as by Violence of Explosion

MINERS trapped in underground excavations during mine fires or after explosions may frequently save themselves from the peril of deadly gases by the erection of barricades of cloth, board, coal or rock, states the U. S. Bureau of Mines, which has completed a study of the subject. The Bureau of Mines has a record of 275 lives being saved in coal mines by the erection of barricades. The bureau is confident that hundreds of other lives might have been saved if entombed miners had possessed a thorough knowledge of barricade construction.

After many mine disasters in America and in foreign countries examination has shown that many of the men found dead had escaped the violence and flame of the explosion but had succumbed to the afterdamp. The evidence collected shows that at 140 disasters 1,477 persons were killed outright and 1,391 were overcome by afterdamp.

Sometimes miners have traveled long distances from their working places before meeting deadly gases, and groups of men have been found dead in a remote section to which they had retreated to escape the afterdamp. Again, men have been found dead near a pile of brattice material which they did not use because they did not know that a barricade would be of value. After the Reilly mine explosion in Pennsylvania in 1922 several of the men rescued said that they knew nothing about the erection of barricades, and there must be many miners unaware of this method of escaping death.

The following practical recommendations for the guidance of miners entrapped at mine disasters are made by the Bureau of Mines: When entrapped by gases from fires or explosions and forced back into workings in which there is comparatively good air, keep uppermost the thought of building a bulkhead or stopping and collect tools, timber, canvas, water, dinner buckets, hay from the stable, and anything else that might be useful.

If possible wherever air is used the barricade should be placed so that a valve in the compressed-air pipe line

will be inclosed in the barricaded area. The valve should be opened to furnish additional air. If there is no compressed air, the miners behind a barricade should either lie or sit on the floor in the hope that the rescue crew will find them before they are overcome. In this relaxed position they will breathe much less of the contaminated air than they would if they exerted themselves.

As soon as a place is chosen for a barricade, its erection should begin, for the gases often travel quickly. The ventilation should be shut off as soon as possible by the opening of doors and the hanging of brattice cloth or by the moving of a door to a new place across an entry. The permanent barricade should be started 50 to 75 ft. from the brattice cloth. Always barricade off as much of an entry, room, drift or crosscut as possible, so as to provide a maximum quantity of air. Before constructing a bulkhead make sure that there is no manway or other connection with other workings through which gases could pass. At some place outside of the first stopping, if more than one stopping is built, place a sign of some kind to show that men are behind it.

If a barricade be made of lumps of coal, slate or other rock, build two walls 2 to 3 ft. apart and fill the space between them with fine material or mud. The stopping must be airtight. Board stoppings are not as easily made gastight as those built of dirt or rock and dirt. All chinks and holes in the barricade should be stopped with clay, raps, clothes and similar material.

Coal miners should remember that they should not barricade themselves in any working or other place that gives off methane, for the firedamp may accumulate and be ignited in some way, causing the death of the whole party. If a piece of pipe is available it should be placed through the stopping and plugged at the inner end, in order that the air outside the barricade can be tested by removing the plug.

After the barricade has been built, the men should keep as quiet as possible so as to conserve the oxygen present. However, occasionally somebody should walk around so as to mix the air. All the men should not congregate in one place.

When the bulkhead is erected test it for leaks by means of a candle or carbide lamp. The way in which the flame of a lamp or candle burns will show the condition of the confined air and to what degree the oxygen is being consumed. All flame lamps should be extinguished, in order not to consume any more oxygen than necessary; also it is desirable not to use oil, carbide and electric batteries needlessly.

Men should signal frequently by pounding on the air or water pipes if there are any, or on the rib or the roof. If, during their retreat from gases, miners find any chalk they should carry it with them. Directions for a relief party may be written on doors, or an arrow may be drawn to indicate the course the miners took in retreating. With the flame of a carbide lamp legible letters can be made on timber or rock.

The first barricade recorded in the reports of the Bureau of Mines was built by entombed miners during the fire at the Cherry mine, in Illinois, in 1909. Seven days after the outbreak of fire in this mine a rescue crew met a party of eight men who had barricaded themselves with twelve others, saved later, but had broken through and were making toward the shaft. They had walked over half a mile, past cars and dead mules, in the dark, and in an atmosphere that would not support the flame of a lamp. These men were in

comparatively good condition when found, and they recovered completely.

By bratticing themselves in an emergency shelter, by closing the "creep-hole" or sliding door in a stopping above a compressed-air pump, and then breathing the exhaust from the pump, thirteen men saved their lives in the No. 2 mine of the San Bois Coal Co., at McCurtain, Okla., in March, 1912.

Detailed information regarding the erection of barricades during mine fires or after explosions is given in Miners' Circular 25, by J. W. Paul, B. O. Pickard and M. W. von Bernewitz, which may be obtained from the U. S. Bureau of Mines, Washington, D. C.

The Miner's Torch

An Age of Charts; but Not at the Mines

IN RECENT years recording instruments have been devised to furnish checks on almost every operation carried on in connection with the various industries and the manager of many modern plants can, without leaving his desk, get a pretty good idea of the work of each department and put his hand on any department that is not functioning properly. In fact, the first thing that will attract your attention in some offices is the prodigious number of chart files.

But the manager of a coal mine is not so favored.

I had this brought home to me the other day when the manager of a group of mines, who had had little mining experience, asked me to devise a system for him that would allow him to keep tab on his superintendents; he didn't want his mines to explode if careful supervision would prevent it. After giving the matter a good deal of thought I began to realize that the thing he asked for was not only impossible but that even his superintendents could not depend on automatic devices to any great extent to check up on their mine foremen and assistants.

Probably the first man whose work you would want to check inside the mine is the fireboss; he leaves his mark in every working place, and if you go to the working places you can see his mark—that is the only way to find out how he has been spending his time.

Then come the men who sprinkle the headings and the working places. If you travel the routes they travel you may be sure they have carried out instructions, but not otherwise. Wait a minute, says someone; how about taking psychrometer readings in the return airways to see whether the air is saturated; if it is saturated you can feel sure that there was plenty of moisture along the traveling ways. Guess again. Even with the dry atmosphere characteristic of our Western mines the air as it travels through the workings of these mines manages to get enough moisture from somewhere to practically saturate it.

The trip riders who are supposed to keep a light prominently displayed on the rear end of each trip—who will check them?

And how about the numerous inspectors who look after the haulage ropes and the mine-car couplings and wheels and the mining-machine cables and swinging trolley wires, etc., etc.; what kind of a recording instrument will furnish a record of their activities?

The section bosses who supervise the timbering, tamping, shooting and loading of bug dust—how will you keep tab on their activities from the outside? Many an explosion could be traced back to one of these bosses, and the evidence would be full and complete, but such checks are not welcome.

The manager of a coal mine is dependent on his superintendent and the superintendent is dependent on his engineers and foremen and these men in turn are dependent on their assistants, and so on down the line. If the manager, the superintendent and the mine foreman and his assistants are competent to give orders and all of these orders that are passed down the line are carried out, things probably will move along smoothly and satisfactorily, but unless some or all of these "order givers" check up occasionally on the "order takers" you can be quite sure that the time will come when some of the orders won't be passed on down the line, or if they are they will not be carried out.

There may be a way to relieve the conscientious mine manager of some of the worry incident to his position (responsibility for explosions, etc.) other than the "see-for-yourself" method I have suggested above, but if there is I haven't discovered it.

Relative Value of Various Inert Gases in Extinguishing Mine Fires

HITHERTO the inert fire gas mainly used in the putting out of mine fires has been the carbon dioxide made by the fire itself, which has a valuable power of combating the flame when the air in which the fire burns is sealed so that oxygen cannot enter. The question of the use of inert gas was quite generally discussed at a recent meeting of the Coal Mining Institute of America. Joseph J. Walsh, Secretary of Mines of the State of Pennsylvania, declared that a small fire should never be sealed. A miner's lamp sealed in a chamber would not go out but would continue to burn because it would not create enough carbon dioxide or consume enough oxygen to provide its extinguishment. The fire should be at least large enough to involve the width of a single chamber.

Answering R. D. Hall, who said that C. Tarleton, general manager of the West Virginia mines of the Consolidation Coal Co., had declared that the return could not be sealed first in a bituminous mine, Mr. Walsh said the fire should never be sealed at a point closer than 1,000 ft. from the seat of the conflagration. In reply to the same questioner, who stated that B. F. Tillson had declared that he had maintained combustion in a producer with air containing only 5 per cent of oxygen, Mr. Walsh asserted that an investigator has found that the glowing coals ceased to glow as soon as fed with air containing 10 per cent of oxygen. Questioned as to the quantity of carbon dioxide in the flue gases with which he proposed to flood the mine workings to the exclusion of air, Mr. Walsh said that he had regarded the quantity of oxygen in the gas as the determining factor.

J. W. Paul said that carbon dioxide had little more effect than nitrogen in blanketing a flame. He said, and A. C. Fieldner supported him, that the carbon dioxide had more effect only as it was of greater specific gravity and had a higher specific heat. The weight of carbon dioxide is to the weight of nitrogen as 44 is to 28.

Harry Pythyon described an incipient fire started at

Belle Vernon on the outcrop of the Pittsburgh seam by a policeman who collected and burned the garbage of the village in the holes made by small openings excavated to obtain fuel for local consumption. The village authorities refused to be responsible for the fire though started by their employee in what was laid out as a village street. He was asked by the Department of Mines to put out the fire, and obtaining help from the Pittsburgh Coal Co., he had several holes drilled and erected a pump with which he endeavored to flood the area.

The fire was not extinguished even though it was sealed. Finally he backed his Ford over one of the boreholes and let the engine run, exhausting the gases into the hole. With this the fire was finally extinguished. He thought the gases from large internal-combustion engines might be used with profit in extinguishing fires, though he admitted that as a rule they would be deficient in volume.

Someone wanted to know why even a small fire could not be extinguished by the increasing oxygen depletion resulting from the absorption of oxygen by the exposed coal faces. Mr. Walsh said that an experiment had been tried in the anthracite region in which the air was sealed tightly for a month. At the end of that time the air in the sealed area contained 19.20 per cent of oxygen.

One of the members declared that the absorption of oxygen was more rapid in bituminous than in anthracite mines. Mr. Walsh added that flushing a burning coal area with earthy materials suspended in water had not proved a successful way of quenching a mine fire.

Company Laundries for Mining Towns

BY W. F. BOVARD

President, Keystone Coal & Coke Co., Greensburg, Pa.

OUR laundry installations at the mines of the Keystone Coal & Coke Co. have proved successful beyond all expectations. It is a great gain to rid the miner's kitchen of the large steaming washtub with its malodorous clothing, which filled the house with steam

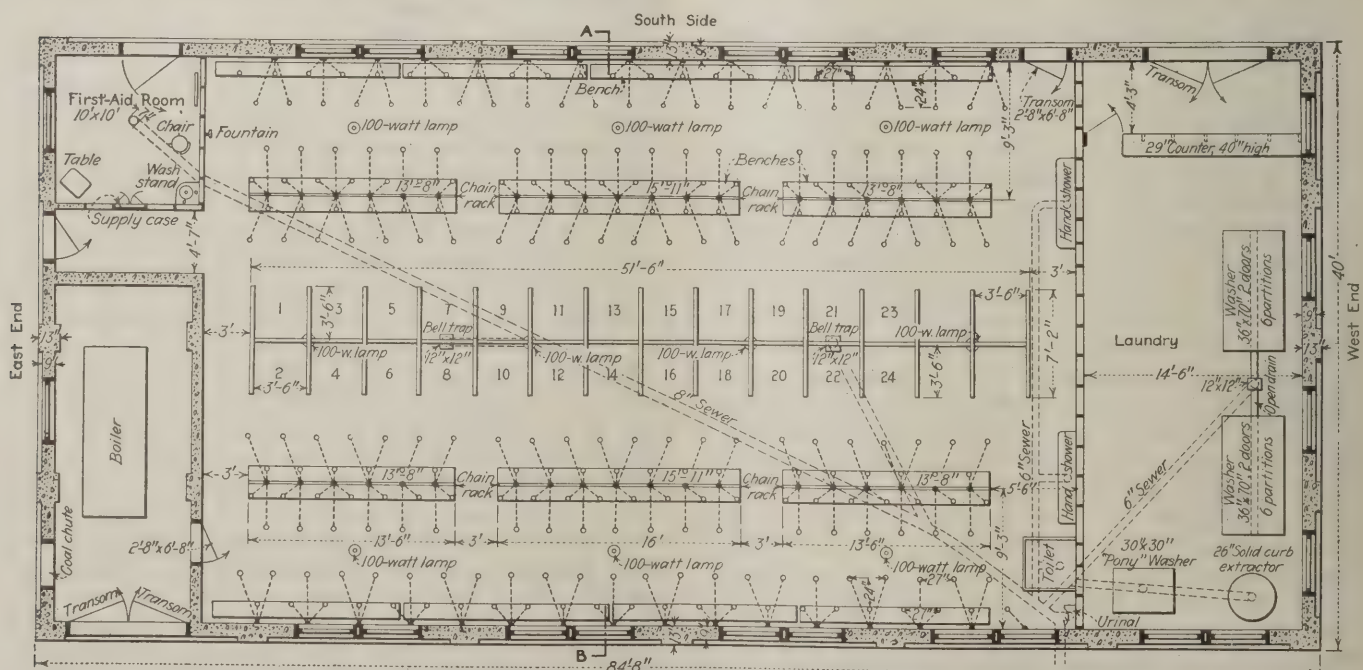

Bathhouse of Keystone Coal and Coke Co.

Radiators behind the wall benches keep them warm and comfortable for those using them when undressing and dressing. This elevation is that of section AB as shown on the plan at the foot of the page.

and rendered the home unhealthful. Now the clothes are bundled weekly and taken to the laundry, where they are passed through the most sanitary washing process that can be conceived. Naturally some of the employees' wives showed some reluctance to make use of this facility, but as time wore on they more and more recognized its advantages, and now the laundries are used by 90 per cent of the community, and every user is well pleased with the change.

No direct return has been derived from this service, our charge to employees actually only offsetting the cost of material used. At our Crows Nest village the laundry consists of two 36x70-in. washers, one 30x30-in. washer and one 26-in. extractor. These units are capable of handling forty washings per day. At present we wash the clothes of only thirty families per day at a total cost of \$13.80. We charge 25c a wash, sustaining a loss of \$6.30 a day, but the benefits obtained are well worth the financial outlay.

Plan of Bathhouse, First-Aid Room and Laundry, Crows Nest Mine, Keystone Coal & Coke Co.

Company Doctors in West Virginia Field

IN A REPORT on "Life in a West Virginia Coal Field," published by the American Constitutional Association, of Charleston, W. Va., a record is made of conditions in 58 mining towns in Kanawha, Fayette, Boone, Raleigh, Logan and Putnam Counties. This investigation was made by Miss Margaret H. Bottum, a community sociologist. The report says that in one section of the field studied there were four mining towns with a combined population of approximately five thousand. They are served by one doctor, assisted by a capable full-time trained nurse.

Six cases of typhoid were reported for these towns during the past ten years. This would indicate that sanitary condition in these towns is above par. The fact that one doctor and a nurse could adequately serve so many people proves that much attention has been paid to the protection of the health of the citizens in the towns they serve.

If one doctor could satisfactorily serve the needs of a community having five thousand population, according to this ratio, eight doctors would be sufficient for Charleston, a city of forty thousand population. But this city has 110 doctors and about as many nurses.

The reason for the existence of "the company doctor" is well explained in bulletin 117, 1923, issued by the Children's Bureau of the U. S. Department of Labor dealing with mining town life, a quotation from which is as follows: "Probably the most serious drawback to living outside the company town was the problem of securing a physician in case of illness. The independent settlement referred to was 15 miles from the nearest private physician, and without telephone." This is an accurate description of the situation in regard to many small, independent towns and rural communities that are too small to support a physician.

With the establishment of the mining town arises the necessity of providing medical care for the people living there. Over a period of many years of actual practice, the plan of collecting monthly subscriptions from the payroll to provide for medical assistance, a sort of health insurance, has proved most satisfactory to employees, employers and physicians.

The monthly subscription ranges from \$2, the high-

est payment for families, to \$1.50 the highest charge for single men. The rates vary somewhat in certain communities, but as given they are those in common use throughout this coal field.

There are 53 physicians in mining-town practice in the towns visited, these physicians being paid by monthly subscriptions. Where the communities are small, one doctor serves two towns. There are 34 resident physicians; 15 towns are within 2 miles and 9 towns are from 3 to 7 miles from their doctors.

At the present time there are less than a half-dozen community nurses employed in this section. This is explained by the fact that, as a rule, they are maintained at the expense of the companies, which have not recovered as yet from the long periods of strike and business depression of the past few years. In several towns visited the companies are contemplating obtaining a public-health nurse who will work under the supervision of the full-time county health officer.

Government Finds It Cheaper to Buy Coal

OPERATED for a short time in 1922 by the Alaska Engineering Commission, now called the Alaska R. R., with funds supplied by the Navy Department, the Chickaloon mine in Alaska served to enable a large-scale test to be made of the coal of that vicinity for naval use. Full results of the tests were not made public, but the general conclusions were that the coal makes a good quality of bituminous fuel. However, the navy decided that under present conditions it could transport privately mined coal from the Atlantic seaboard to the Pacific coast for use at a lower total cost than the Alaskan coal could be, in view of the costs of production and transportation along the coast to the states of Washington and California. Moreover, the best Eastern coal is slightly more desirable.

The Chickaloon mine is one of three governmental operations in the Matanuska field of Alaska. None of these is being operated by the government, which does not propose to mine coal so long as private mines are being operated. The Eska mine has been worked for several months by the Evans-Jones Corporation since the destruction by fire of the equipment at the mines of that company.

Chickaloon Mine of Alaska Engineering Commission.

Convinced that it ought to find out something about fueling possibilities on the Pacific Ocean, the United States Government started three mines in Alaska, but, partly from a feeling that it should not pit the unbounded resources of the nation against pri-

ivate capital and partly because the price of coal at the point of use was higher than better coal obtainable elsewhere, the government closed two mines down and turned the third over to a private company.

Will Midwest Rivers Reduce Cost Of Illinois Coal To Chicago and Northwest Consumers?

WILL river traffic in coal spread westward to include the Mississippi from St. Louis to Minneapolis and from St. Louis up the Mississippi and Illinois rivers through a canal to Chicago and Lake Michigan? Will southern Illinois and Standard district coal thus enter the Lake trade by an all-water route? The questions are not new but with the steady development of waterways in the Middle West they get more and more discussion. Every car shortage brings them to the fore and every word about raising rail rates on coal throughout the Middle West sets interested men to work with pencil and paper figuring how much the cost of Illinois coal could be reduced by water haulage.

Only the extreme river enthusiast can see possibilities of hauling Illinois coal from the great southern fields of Franklin, Williamson and Saline counties by water northward. There are two main obstacles: The

field is crisscrossed with a network of railroads already and there are few mines that could make river connections without tremendous expense. The necessary thing would be to set up some sort of railroad shuttle service between the mines and river loading points. Such a road as the Wabash, Chester & Western has possibilities for this sort of thing. But the cost and degradation of handling coal from a mine tippie into a railroad car and again from a car into a boat twenty miles away on the Mississippi or Big Muddy would be considerable.

On the other hand, the Belleville mining field, directly east of St. Louis and only 10 or 12 miles from the river, offers a better opportunity for river loading. Steam- or electric-railroad service between field and river tippie generally is recognized as feasible. In fact one company has used such service for years between some of its mines and a river tippie in East St. Louis. Such lines as the St. Louis & O'Fallon and the St. Louis, Troy & Eastern are well located to run a shuttle service that could be made, by the extension of tracks in the mining field, to serve

many a mine. Degradation would not be so costly a factor here because the Belleville field depends to a less extent upon perfect sizing of coal.

From St. Louis northward there is no question among well-informed men that water movement of coal could far undercut present freight rates. The rate from Belleville to Chicago now is \$1.85. It is confidently declared by experienced river and coal men that this could be reduced \$1 with river traffic properly developed. The astonishing but sober estimate for moving coal by barge from a St. Louis river tippie to an unloading point in Chicago is 50c. This is based upon the assumption that a strong and continuous market for Belleville coal could be found in or around Chicago and that the river fleet was made up of big modern towboats of approximately 1,000 hp. and enough barges to guarantee against loading and unloading delays.

"But there can't be any such strong and continuous market because there are not enough coal consumers with water frontage in the Chicago district," say the unbelievers. A survey made in 1915, however, shows that at that time there

Headpiece shows towboat Nokomis with famous tow of St. Louis-to-St. Paul coal. In 1915 this shipment of 3,000 tons on six barges was loaded at St. Louis and delivered in fourteen days at the Twin Cities. W. K. Kavanaugh, who dreams of hauling coal up the river and grain down, made the shipment to prove that it could be done.

was a coal consumption of 5,000,000 tons a year along the Illinois state canal between Joliet and Chicago either at the water's edge or within short trucking distance.

There are those who say: "When you begin talking about hauling coal from barges inland to Chicago consumers you spoil the whole program. It will cost so much to unload boats into cars and haul the cars to destination that all the freight saving is lost." But the river men declare that a vast tonnage could be handled from the canal by trucks at less cost and in shorter time than is possible with railroad equipment and they add that underground conveyors would be feasible for consumers whose plants are near the water but too far away for direct unloading.

WOULD DEVELOP RIVER SYSTEM

W. K. Kavanaugh, of St. Louis, president of the Southern Coal, Coke & Mining Co., is one of the men who believe in water transportation. For years it has been his firm belief that it is practicable to develop a system of river shipping of coal from Mississippi River points clear up to Minneapolis and St. Paul and bring ore, grain and other bulky northwest freight down as return loads. To prove it he and Edward Goltra, veteran St. Louis river transport men, made a single shipment of 3,000 tons of mine-run coal to the Twin Cities without expectation of getting a return load.

That trip is famous. The coal was hauled from the Shiloh mine of the Southern Coal, Coke & Mining Co. by rail to the company's river tipples at St. Louis and loaded into six barges. The staunch towboat Nokomis took the tow and headed north. Mr. Kavanaugh's directions to the captain were to deliver that coal into the Twin Cities within ten days. The tow plowed its way up the river—a trail blazer.

There was no report of it for several days. Then word came back that the Nokomis and her 3,000 tons of coal had lost two precious days at Rock Island, Ill., trying to get a government river pilot, without which the northward trip could not be made. The next word was that two more equally precious days had been lost because of a broken pitman strap on the steamer.

Mr. Kavanaugh took a train and journeyed up to St. Paul, however, and met his shipment a few miles below the city. He went aboard and rode into town with the coal, stepped

ashore, and, without previous cultivation of the market, disposed of the whole cargo before nightfall at a price which he says was "a good profit." The captain of the Nokomis could account so well for all the excess time consumed over and above the specified ten days that Mr. Kavanaugh, with the money for his coal in his pocket, figured the experiment a success.

Today there is even more serious contemplation of hauling coal up to the Twin Cities and of bringing grain and ore down. "But it must be considered only as filled," according to Colonel T. W. Ashburn, in charge of inland waterway transportation for the War Department, which owns a number of big barges now in freight service on the Mississippi. The main sources of revenue, he thinks, will be general cargo. Ever since war days the government's enterprise, The River Transit Co., has been handling great volumes of general freight up and down the river between St. Louis and New Orleans at a profit, and there is reason to believe that the same thing can be achieved from St. Louis northward.

Railroads are freely charged with trying to choke this sort of river traffic to death, however. Congressman Cleveland A. Newton, of St. Louis, has publicly stated that there is organized railroad effort to strangle river shipping and that it ought to be stopped. It is his idea that all transportation systems in this country, whether rail, water or highway, ought to be welded into one great system. The strangulation method, he says, is simple. Railroads, realizing that the river serves mainly only those towns on its banks, proceeds to reduce to ridiculously low levels, rail rates into those towns at the expense of the towns a few miles back from water, thus stealing river freight.

This sort of competition between rails and water on coal is not so easy to apply. Coal men who see possibilities for river shipment of coal into the Chicago switching district declare there could be no distinction made by railroads between consignees on water front and any others because the rate fabric within the switching district could not be so juggled. They feel there is enough coal business at the water's edge to support a large river coal transportation system and that therefore some day it will be established.

There can be no shipping between

St. Louis and Chicago until an extensive program of canal development now under way is completed between LaSalle, the present north limit of Illinois River navigation, and Joliet, on the Chicago Drainage Canal. An appropriation of \$20,000,000 has been made for this project with an additional \$8,000,000 for water-power development, and some of this money has already been spent. It was the original intention to have this state waterway open for barge navigation by 1924, but delays of various sorts, political and otherwise, have held the work back in spite of pressure brought to bear upon laggard state officials by agitators for the Great Lakes-to-the-Gulf waterway.

The canal eventually will be open for shipping, however. What about coal traffic then? There are one hundred different answers to the question supplied by every one hundred men in the coal business. Meanwhile freight rates on coal to Chicago from Southern Illinois continue at \$1.95 instead of the "dollar" so freely prophesied by a few river boosters; from Belleville, \$1.85 instead of 75c., and \$2.16 from western Kentucky, a coal field that often ships heavily to Chicago and which can put coal on water with considerable ease.

Coal-Mine Development In West Virginia

Fifty new mine plants were put in operation in West Virginia during the fiscal year ended June 30, 1922, according to the annual report of the State Department of Mines. In the same period 43 new power plants were constructed and 81 fans.

One of the most important equipment improvements made, indicating at the same time the growth of the industry, was the purchase of 8,235 mine cars, the Logan field leading with 1,329, the McDowell mines coming second with 1,144 cars, followed by Fayette mines with 1,113 and Raleigh mines with 1,070. In all 85 new tipples were built, Logan having 9 of such structures to its credit, Raleigh 8, Fayette 7, Greenbrier 7 and Monongalia 7.

Companies operating in the state built 828 new houses for miners, Wyoming mines building the largest number, 114. Another important addition to equipment was locomotives. There were 187 new locomotives put in use, Logan mines obtaining the largest number, 35. McDowell and Raleigh county mines purchased 23 and 24 locomotives, respectively. There were 124 new mine openings; Preston County led in such development, with the opening of 18 new mines, McDowell County ranking next with 11 new openings.

News Of the Industry

Wage Parley Begins at Jacksonville; John Lewis Presents Miners' Demands

(Special Dispatch to Coal Age)

JACKSONVILLE, FLA., Feb. 11.—The joint conference of union miners and bituminous-coal operators of the Central Competitive Field organized here this morning with Michael Gallagher, Ohio operator, chairman; William Green, secretary of the miners' union, as secretary, and Ezra Van Horn, Ohio operator, assistant secretary.

John L. Lewis, international president of the miners' union, made a brief statement of the miners' demands, reading the report of the scale committee adopted at the Indianapolis convention, which instructed the miners' representatives to "obtain the best possible agreement on the basis of no reduction in wages," and recommended that the contract extend for a period of four years. Van Horn then moved that the conference adjourn until 10 o'clock tomorrow morning.

Directly afterward the operators went into caucus, but did nothing. Statements by the operators indicate that they are not organized and will

be unable to act as a unit until they confer further and determine upon a counter offer to the miners. Operators are here from all four districts. They are as follows: Illinois—Rice Miller, L. H. Smith, E. C. Searls, George B. Harrington, W. J. Spencer, C. H. Kraus, H. C. Perry and Harry C. Adams; Indiana—David Ingle, M. L. Gould, J. A. Templeton, Hugh Shirkie, W. J. Freeman, A. M. Ogle, E. D. Logsdon, and P. H. Penna; Ohio—Michael Gallagher, S. H. Robbins, Ezra Van Horn, R. L. Wildermuth, W. H. Haskins, T. R. Biddle, J. S. Jones and A. A. Augustus; Western Pennsylvania—J. A. Donaldson, J. M. Armstrong, W. M. Henderson, T. W. Guthrie, John A. Bell, Jr., R. C. Crawford, M. W. McClain and A. M. Marion.

Miners are represented in the conference by their three International officers and the Central Competitive Field scale committee, named during the Indianapolis convention, which ended Feb. 2.

Industrial Relations Program Of A.I.M.E. and N.S.C.

Co-operating on a safety and industrial relations program the American Institute of Mining and Metallurgical Engineers and the National Safety Council will hold sessions on Monday, Feb. 18, Tuesday, Feb. 19, and Wednesday, Feb. 20, at the Engineering Societies Building in connection with the annual session of the first-mentioned society. At Monday's session the various subcommittees of the Industrial Relations Section will make their report. At the meeting of Tuesday W. W. Adams, of the U. S. Bureau of Mines, will read a paper on "Mine Accident Statistics" based on the carefully collected experience of member companies, using of course only aggregated figures, and not revealing company names. R. L. Sanford, of the U. S. Bureau of Standards, will relate his progress in the magnetic testing of hoisting rope. T. T. Read, of the U. S. Bureau of Mines, will deliver an address on the efforts of that institution to promote safety.

On Wednesday morning, Arthur Notman presiding, Dr. A. J. Lanza, who has just returned from a long foreign trip in the interest of occupational-disease prevention, will give an address entitled "Some Recent Experiences in Australasia"; Robert E. Tally,

an address on industrial relations; L. K. Silcox will speak on the same subject, emphasizing the dual responsibilities, and D. L. Sterling, secretary, Australasian Institute of Mining and Metallurgy, will give an address on a subject not yet announced.

On Wednesday afternoon Sidney Rolle, secretary of the Industrial Relations Committee, will introduce G. M. Gillette, general manager, Consolidation Coal Co., Maryland Division, who will speak on "Vital Factors in Industrial Relations." John T. Ryan will discuss "Industrial Relations in the European Coal Fields" and D. Harrington "Dust and the Health of the Miner." W. R. Chedsey will present a paper on the living wage.

Herrin Again

Eight companies of Illinois-state troops on Feb. 9 took over the administration of law in the region around Herrin, in "bloody Williamson County," scene of the mine massacre of 1922. This is the second time within a month that troops have gone in to stop open warfare between Ku Klux Klansmen, who have been recklessly raiding various dives and homes of liquor suspects, and Knights of the Flaming Circle, organized to oppose the Klan.

Inspectors Soon to Report on Shanktown Disaster

Mine Inspectors Nicholas Evans, of Johnstown; Thomas S. Lowther, of Indiana, and Thomas J. Lewis, of Punxsutawney, on Feb. 8 completed their examination of the Lancashire mine, at Shanktown, Pa., in which 36 men lost their lives in a gas explosion on Jan. 24. The inspectors will formulate a report on their findings and submit it to State Secretary of Mines Joseph J. Walsh.

Coal operators are generally of the opinion that the inspectors located the source of the gas which filtered into the mine and caused the explosion. It is the belief of the producers that the commission will strongly recommend measures meant to prevent a recurrence of the disaster that occurred in the Shanktown plant. Agents representing compensation insurance companies are examining the mine and may file statements covering the points of mine equipment, etc., which they believe need replacement. On going to press we learn that the Coroner of Indiana County will hold an inquest Feb. 12.

Form Mine Safety Association In Central Pennsylvania

Sixty representative coal operators of Cambria, Blair, Clearfield, Centre, Somerset, Westmoreland and Indiana counties, Pennsylvania, met in Johnstown on Thursday evening, Feb. 7, and organized a mine safety association. The purpose will be to co-operate with the U. S. Bureau of Mines and to obtain a safety or emergency car for the central Pennsylvania district. The importance of having several emergency stations for possible disasters such as occurred at Shanktown recently was advocated by P. J. Morrissey of Johnstown, who presented an outline of the proposed work of the association, whose purpose, he explained, will be to establish emergency stations to which all mines in trouble may call and receive aid by crews as soon as possible.

M. J. Bracken spoke of the necessity of co-operating with the Bureau of Mines and a representative of the Bureau of Mines outlined plans for the work of organizing the state operators for the purpose of obtaining a central Pennsylvania relief car. To further the work, the following were named as a committee: P. J. Morrissey, Pennsylvania Public Service Corporation; John R. Thomas, state mine inspector; Timothy McCarthy, superintendent of the Clearfield Bituminous Coal Corporation; William Patterson, Pennsylvania Coal & Coke Corporation, and A. E. Roberts, Revloc Coal Co.

Death Claims Edwin Ludlow In Muskogee

After an exceptionally brilliant career as a mining and railroad engineer Edwin Ludlow passed away Feb. 10 in a hospital at Muskogee, Okla., after a short illness, of pneumonia. He was almost 66 years of age.

The deceased was born at Oakland, Long Island, N. Y., March 12, 1858. He attended the Flushing Institute and the Columbia School of Mines, being graduated from the latter institution in 1879.

From 1879 to 1881 he was assistant engineer on river and harbor work at Philadelphia, leaving this position for Mexico, where he was one of the engineers on the Mexican National R.R. running from Laredo, Texas, to Mexico City. That company being in financial straits he returned to the United States and became assistant superintendent and later superintendent of the Mineral R.R. & Mining Co., at Shamokin, Pa. This was one of the subsidiaries of the Pennsylvania R.R.

Later he became superintendent of the Union Coal Co., a concern which had just leased two of the Mineral company's collieries. When in 1885 Major Stearns was made general manager of all the coal properties of the Pennsylvania R.R. Co. Mr. Ludlow was promoted to the superintendency of the Mineral company. This was the time when he introduced into the anthracite region water-tube boilers and chain conveyors.

In 1899 he was asked to take charge, as superintendent, of the mines of the Choctaw, Oklahoma & Gulf R.R., Harts-horne, Okla., then a virgin coal field. While employed there he married Miss Anna Wright, who, by her ability as a hostess, in later years added much to the social events of the A.I.M.E. The mining field that Mr. Ludlow opened was some 80 miles long and communications were not of the best. In consequence he did not find time lagging while directing the operations of the field.

After ten years of Oklahoma Mr. Ludlow returned to Mexico, becoming general manager of the Mexican Coal & Coke Co. at Las Esperanzas. Here he succeeded so well that his company made \$600,000 in a single year, but the operation of the mines became increasingly difficult and the success of his work brought rivals in the field.

In 1911 he became vice-president and general manager of the New River Collieries Co. at Eccles, W. Va., and in 1912 exchanged that position for a similar one with the Lehigh Coal & Navigation Co., at Lansford, Pa. This position he occupied till 1919, when he resigned to become a consulting engineer. In 1921 he became president of the American Institute of Mining and Metallurgical Engineers and traveled extensively over the country in its interest.

In Mr. Ludlow the mining engineers have lost one of the most aggressive of their leaders. He was from the first a firm believer in modernizing equipment, and he took an active interest in mining education and industrial relations. None more than he believed

Edwin Ludlow

in the importance of membership and co-operation in the work of engineering societies, and those who were at any time under his direction contributed generously to the technical societies' programs and to the columns of the technical press.

New Record at Zeigler Mines

The cold weather of January so increased the demand for coal that a new production record was made at the Zeigler mines, in Illinois, 310,077 tons having been hauled to the surface, prepared and shipped by the Bell & Zoller organization during the month. The daily average production was approximately 12,000 tons. The highest daily run of the mines was made on Jan. 23, when 14,205 tons was hoisted to the surface.

To handle the coal required 6,752 railroad cars, which would make a train which would reach about 63 miles, or very nearly the distance from Chicago to Rockford, Ill. A train of this length would require 137 engines to move it, or, divided into separate trains, there would be approximately 50 cars to each engine. Production like this necessitates the shipment of about five such trains each working day.

Ten years ago, in January, 1914, what was then a record of production for the Zeigler mines was established when 58,000 tons was loaded and shipped. The 1924 record was nearly six times greater.

Pittsburgh Coal Co. Back in Fold

The Pittsburgh Coal Co., which resigned from the Pittsburgh Coal Producers' Association at the time of the Cleveland settlement, in August, 1922, has rejoined the association. At a meeting Feb. 8 Pittsburgh district operators decided to attend the wage conference at Jacksonville. They had some difficulty in reaching an agreement and would not give out an official statement.

Sees Mergers as Only Hope for Some Companies in 1924

"Consolidate!" is the cry ringing through many a coal field. For a year fitful starts have been made to bring together favorably located groups of mines. Now the movement is definitely on its way. It is absorbing direct attention in central Illinois, in Saline County, Illinois, and in both ends of Kentucky. The first direct accomplishment was in the fusion of the Taylor Coal Co. and the Bickett Coal & Coke Co. several weeks ago, bringing together a group of six good mines in southern Illinois backed by Cassatt & Co., the same financial interests which are behind the Old Ben Coal Corporation, long a dominant operating concern in southern Illinois.

The proposed consolidation of central Illinois operators took a definite turn a month ago when one of the active operators there proposed that a majority of the tonnage of the field, other than that produced by the Peabody Coal Co., the biggest influence in the field, be pooled. The plan was for each participating company to put its properties under the control of an operating company, the tonnage to be sold through one agency. This plan failed. Nevertheless the consolidation movement did not stop. A new plan is now under consideration which would group a number of properties under one ownership and leave the proposed company and the Peabody Coal Co. in control of so nearly all the No. 5 vein tonnage that ruinous competition would be reduced.

The various other proposed groupings have advanced far enough to require engineering reports and appraisals and for the collection of bushels of options on this and that.

"There is no doubt," said one of the wisest coal operators in the Middle West, "that consolidations must come—and lots of them. There is no other way that I know of for a good many companies to weather 1924. This country is going to require its usual 500,000,000 tons of coal, but if the 1923 number of operators try to stay in business, they are going to fall by hundreds. The only question in my mind is: Will enough of them be willing to make mutual concessions now in order to form consolidations on sound bases, or will too many of them insist upon independence until they are driven to the wall?"

"It is painful, in a way, to see all this going on, but it is exactly what the coal industry needs to make it healthy. There is no better way to reduce the number of mines and miners in this country than by voluntary grouping of operating interests, which would cull out the high-cost and undesirable mines, and put the whole industry on a firm, substantial foundation."

A.I.M.E. Meet in Birmingham

The American Institute of Mining and Metallurgical Engineers has accepted an invitation of the Alabama Mining Institute and the Birmingham Chamber of Commerce to hold its autumn meeting at Birmingham. The meeting probably will be held in October.

New Safety Film for Bureau of Mines

In memory of his father, the late F. S. Peabody, Stuyvesant Peabody has agreed to finance a new Bureau of Mines film showing the application to coal mining of the most advanced safety practice. The only motion pictures dealing with the safety problem in coal mines which the Bureau of Mines now has for display are old. They were made at a time when the technique of motion-picture making had not reached its present stage of development. Since they were made there also has been much progress in safety practice. For these reasons there is a great demand for the production of a high-class film which will include the latest safety developments.

Congress never has appropriated for films to be used in connection with the Bureau of Mines' work. The many motion pictures being displayed under Bureau auspices have been made possible by contributions from industry. Most of these pictures, however, deal with technical problems from an economic point of view.

Fewer Mine Fatalities in 1923

Accidents at coal mines in the United States in 1923 caused the death of 2,452 men, according to a report by the U. S. Bureau of Mines. Of these fatalities, 2,249 occurred as the result of accidents underground, 46 were due to shaft accidents, and 157 to accidents in and around surface plants. The production of coal during the year was 641,476,000 tons; hence the fatality rate for the year was 3.82 per million tons, as compared with 4.15 for 1922.

This reduction of 8 per cent in the fatal-accident rate per million tons of coal produced in 1923 is equivalent to the saving of 210 lives.

Falls of roof and coal, which generally account for nearly half of all deaths in coal mines, were responsible for 1,158 fatalities in 1923, which represents a rate of 1.81 per million tons, as compared with 1.90 in 1922. Haulage accidents underground usually cause

William Kelly

Nominee and probably next president of the American Institute of Mining and Metallurgical Engineers; general manager, Penn Iron Mining Co., Vulcan, Mich., and Republic Iron Co., Republic, Mich.

about 18 per cent of all fatalities, and the reports for 1923 show that 413 deaths were due to this cause, indicating a rate of 0.64 per million tons, as against 0.72 for the previous year. Gas and dust explosions killed 372 men, the fatality rate being 0.58; the previous year's rate was 0.65. Seventy-five deaths were due to electricity, for which class of accidents the fatality rate per million tons was 0.12 as compared with 0.16 the year before. Powder and other explosives caused 114 deaths, representing a rate of 0.18 as compared with 0.19 for 1922.

Production of 10,225,000 Tons in 1922 Shows Importance of Soft-Coal Strip Pits

The growing importance of strip pits as producers of soft coal is indicated by the fact that in 1922 10,225,000 tons—equivalent to 2.4 per cent of the total output—was produced by the strip mines, according to the U. S. Geological Survey. They employed 9,108 men. The total number of steam and electric shovels used was 379. The mines at which these shovels were employed produced 9,886,431 tons of coal. In addition,

338,711 tons were produced at workings where some method other than a steam or electric shovel was used in removing the overburden and loading the coal.

Ohio leads all other states in the tonnage of strip-mined coal. Nearly one-third of the 1922 output was reported from that state. Other leading producers were, in order of rank, Pennsylvania, Indiana, Missouri and Illinois.

Production, Number of Employees and Number of Steam and Electric Shovels At Bituminous-Coal Strip Pits

(a) Includes a small number of shovels used underground.

Miners' Union Prepares to Fight Pinchot Bill

The United Mine Workers, it is announced, are preparing to fight Governor Pinchot's coal bill as introduced in Congress by Senator Borah. It is declared the measure aims at anti-strikes and for that reason organized labor is against it. An official of the miners in Washington is quoted as opposing the bill because it would tie up the funds of the organization and threatens to jail the officers.

The bill provides that in the event of an emergency growing out of a strike threat the President may exercise through a proposed coal division of the Interstate Commerce Commission all the powers conferred by the Lever Act in effect during the war.

The courts have interpreted this act as giving the authorities power to enjoin the calling of a strike in any industry affecting the nation's fuel and food supply.

"This is anti-strike legislation in its most vicious form," said the mine workers' official. "Were it enacted the mine workers' union might as well close up shop. Our experience in 1920 convinces us that it would not be a difficult matter to induce a federal judge to repeat what was done by Judge Anderson at Indianapolis, who reduced us to the status of a debating society. His injunction prevented us from giving relief through our own funds to members who were in need. Governor Pinchot may consider himself a friend of the worker, but his coal bill is one of the most destructive blows ever aimed at the miners' union. We will do everything we can to defeat it."

Oddie Putting Finishing Touches on Administration Coal Bill

Basic Fact Finding Proves Knotty Problem—Situation Complicated by Attitude of Department of Justice Toward Trade Associations—
Issuance of Export Certificates Planned

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

After nearly three months of intensive effort, Senator Oddie is whipping into final shape his ideas as to the legislation which will be necessary to carry into effect the recommendations of the Harding Coal Commission. Before making the bill public he is anxious to confer with representatives of the various branches of the industry and with those of the different types of consumers.

One of the knotty problems which Senator Oddie has been called upon to consider is that of basic fact finding. He has acquainted himself with the arguments for and against compulsory reporting of essential data. He has found such wide differences of opinion as to the best procedure in fact finding that he now is considering an alternative suggestion which he believes possesses sufficient merit to justify careful study. At this writing, however, it has not been embodied in the draft of the bill.

The idea is to collect the information through the existing trade associations, both national and local. The reporting is to be done on a voluntary basis with the understanding that the federal government is to have the right to check all returns at any time a need should arise. In this way the federal government would be spared great expense and the industry would not be subjected to federal interference except when suspicion might arise as to the correctness of certain returns.

Under such an arrangement, it is thought, there would be few occasions for the government to exercise its right to audit any statement that may have been made. Even were it to become necessary to exercise it, the checking probably would be confined to a small area and possibly to individual mines.

Such a system probably would have to be supplemented in some way, as there are districts which have no local associations. Senator Oddie sees no adequate reason why a scheme of fact finding may not be worked out through friendly co-operation of trade associations, pledged to give the full picture of the situation with the right to check any returns as an assurance against the small minority which exists in any business which might submit false returns.

Senator Oddie realizes that the situation in this connection is complicated by the policy of the Department of Justice toward trade associations. In the course of the investigations of the Commission of Gold and Silver Inquiry, of which he is chairman, he has been reminded frequently of the uncertainties which have settled down upon all business statistics as a result of the Attorney General's action. He realizes, however, that a coal bill is no place to attempt to settle the status of statis-

tical activities and as he believes the trade associations in the coal industry perform a highly valuable function and are in the interest of the public generally he does not expect any permanent interference with their work.

Senator Oddie also is considering embodying in the bill a provision giving authority to the Cabinet officer in whom the power conferred by the bill will be vested, to effect a plan for the issuance of export certificates on coal, should that official reach the conclusion that such a plan is wise. Senator Oddie is impressed with the need for some certification as to the quality of coal shipped in export trade.

Teapot Dome has so monopolized the attention on Capitol Hill that no great amount of attention has been given to proposed coal legislation, but despite sensational developments in the oil situation, the convention of the United Mine Workers at Indianapolis did not pass without notice. There is little difference of opinion among the lawmakers as to what ought to be done.

The general feeling is that the operators should sign the proposal of the United Mine Workers that present wages and working agreements be continued for four years. There is a general feeling, however, that in such an agreement some provision should be made for flexibility. The thought has been advanced that a clause should be inserted in the agreement providing for automatic adjustments in wage rates

each time there should be a rise or fall in the cost-of-living index figure. If the operators should object to accepting the index number of the Department of Labor, it is believed an arrangement could be worked out to accept the average of the index numbers of the Industrial Conference Board and of the Department of Labor. Any such plan would necessitate putting into the contract detailed provisions for putting the adjustment into effect.

Members of Congress are particularly aware of the inequity worked upon the man with a fixed income by fluctuations in living costs. For that reason, they sense at once the difficulties of a fixed and rigid wage scale intended to apply over a four-year period. They have not forgotten the supplemental agreements of 1917, which caused the strike of 1919. It is realized that if prices should fluctuate as much during the next four years as they have during the past, violent labor troubles would result.

Just at this time Congress is considering revenue revision. This has led its members to acquaint themselves with the economic prospects. They find that the Federal Reserve Board is apprehensive as to the possibility of our being on the verge of another period of inflation. It is recognized that the abundance of gold and the banking situation generally lends itself to the recurrence of an unhealthy boom such as that of 1920. With these thoughts uppermost in mind, many legislators and federal executive officers entertain the hope that some provisions will be made whereby wages in the coal industry will follow the purchasing power of money.

Much satisfaction is expressed in official quarters as a result of the decision of the Pittsburgh district to send a scale committee to Jacksonville. It was not realized in Washington at first that the position of the Pittsburgh operators was being influenced by their doubt as to the legality of an interstate conference. Sight had been lost of the fact that the Attorney General never has expressed himself other than to say that such a conference is illegal. Secretary Hoover's letter to the Pittsburgh Operators' Association was thought to be hardly sufficient since it was his expression, and not that of Mr. Daugherty. Mr. Hoover's conference with the President, however, put the administration on record and cleared the air.

Communications from Pittsburgh show that the operators there, as well as in all other fields, are divided as to which is the better course to take in formulating the new agreement. All agree that the renewal of the present scale carries with it the possibilities of serious consequences, but the alternative is the closure of mines by a strike. No single operator in the Pittsburgh district is advocating a strike rather than recede from what the operators want. The Pittsburgh operators are far from being belligerent, as is indicated by their sending a scale committee instructed only to obtain the best agreement that they can get. One of the reasons they will advance for a contract to run less than four years is that it should terminate in other than a presidential year.

Coolidge Urges Attendance At Jacksonville Parley

After conferring with President Coolidge, Secretary Hoover issued a formal statement Feb. 6 declaring it was the administration's wish that representatives of the bituminous-coal operators and the mine workers in the Central Competitive Field attend the wage conference at Jacksonville, Fla., Feb. 11. The purpose of the statement, it was said, was to set at rest reports that those attending might be attacked as attending a price-fixing meeting in violation of the Sherman Act.

"It is the understanding of the administration" said the statement, "that the conference is solely for the purpose of settling a contract covering wages and conditions of labor. This is intended to confirm my recommendation to certain coal operators' associations on Jan. 26 and to finally quiet rumors on the administration's attitude that have been current during the past few days."

British Columbia 1923 Output 37,000 Tons Below 1922

Total coal production of British Columbia for 1923 is placed at 2,543,675 tons as against 2,580,915 tons for the previous year, or a decrease of 37,240 tons. To arrive at the net output for the year it is necessary to take 87,834 tons from the figure given, as approximately that amount was used in the manufacture of coke or lost as waste. Thus it is found that the net production was 2,455,841 tons, in comparison with a net output for 1922 of 2,511,843 tons, or a decline, in point of value, of about \$280,010. The manufacture of coke increased from 45,836 to 58,000 tons. This was due to the activity of the Michel ovens of the Crows Nest Pass Coal Co.

For comparative purposes the following statistics on total production, in tons are interesting:

	1922	1923
Vancouver Island	1,754,656	1,551,926
Nicola-Princeton	770,890	666,865
Crow's Nest Pass	554,361	744,568
Tellwa Mines	1,008	36
Totals	2,580,915	2,543,675

Production by collieries for 1923 with estimated figures for December follow:

Newly elected president, United Engineering Society; chairman of board, Ingersoll-Rand Co.; past president, American Institute of Mining and Metallurgical Engineers, New York Chamber of Commerce and Manufacturers Export Association.

Engineers Study Industrial Preparedness for War

Industrial preparedness for a possible war was the subject which attracted more than 700 engineers to a dinner at the Hotel Commodore, New York City, on Tuesday, Feb. 5, under the auspices of the Army Ordnance Association and the five national engineering societies, the A.S.C.E., A.I.M.E., A.S.M.E., A.I.E.E., and the S.A.E. Judge Elbert H. Gary presided, the other speakers being Colonel Dwight F. Davis, assistant Secretary of War; Colonel James L. Walsh, chief of the New York Ordnance District, and General John J. Carty, vice-president American Telephone & Telegraph Co.

Colonel Davis explained that work on industrial mobilization has been under way for three years and much progress has been made. The seven supply branches of the government have fig-

ured out what will be required should the country find it advisable to engage in war, and the next question that arose was where can the necessary supplies be obtained. To answer this a survey of the industrial resources of the country is in progress.

Mr. Carty read an address in which he paid a tribute to the part played by American engineers in the last war and emphasized the necessity of being better prepared for the next one.

In an ante-room to the banquet hall was an exhibit of modern developments in munitions, including a 4,000-lb. aerial bomb, ten times the weight of the largest bomb used in the World War. A caterpillar tractor has been produced that will climb a 45-deg. slope at the rate of 30 miles an hour. The Ordnance Department has designed a 75-mm. gun with twice the range of the French guns of the same caliber used in the late war. Newly perfected automatic shoulder rifles bid fair to replace the magazine rifle of World War days. The 0.50 caliber super-machine gun recently developed shoots a bullet weighing four times as much as the 0.30 caliber Browning and throws it nearly three times as far. Although development of munitions is so rapid, Colonel Walsh said that the Ordnance Department would not halt production to await new inventions but would proceed with the manufacture of those certain to give reasonable satisfaction in battle, and which could be made in America in sufficient quantity.

Colonel Walsh recommended complete arrangements being made for the manufacture of munitions on a war-time scale so that if there were any springing to arms overnight there would be arms to spring to. He also urged that engineers aid by forming local committees whose chairmen would comprise a district advisory committee. Furthermore, engineers should become reserve officers, and he expressed the hope that we will some day have reserve ordnance plants which in time of business depression would be given educational orders by the government.

British Miners Produce Short Ton per Man in Single Shift

Presenting a statement of output and production costs for the quarter ending June 30, 1923, of mines producing about 95 per cent of the total quantity of salable coal mined in Great Britain, the November (1923) issue of the Ministry of Labor Gazette says that the production costs, after deducting the proceeds of the miners' coal, were \$3.74 (par) per net ton and the credit balance averaged 70c. (par) per net ton. In three districts costs exceeded proceeds; in other districts credit balances ranged from 2c. to \$1.10 per ton.

The number of workers employed during the quarter was 1,102,380 and the number of man-shifts worked 73,205,708. Based on the tonnage of salable coal mined the average output per man-shift worked was one net ton, the average for the different coal-mining districts ranging from 0.67 to 1.14 net tons. The average earnings per man-shift were \$2.13 (par), the earnings varying from \$1.64 to \$2.69 (par), according to the district.

The accompanying table shows the quantity of coal mined, number of workers and output and earnings per man for the quarters ending March 31, 1922, to June 30, 1923.

Operating Data of British Mines by Quarters

(Shilling at par 24. 3c.; penny 2.03c.)

Quarter Ending	Salable Coal Mined, Net Tons	Credit (+) or Debit (-) Balance per Net Ton, Cents	Number of Workers	Output per Man-shift, Net Tons	Earnings per Man-shift Worked
March 31, 1922	64,549,667	+24	1,020,207	1.0209	2.68
June 30, 1922	59,652,347	-003	1,025,542	0.9968	2.49

Practical Pointers For Electrical And Mechanical Men

How to Keep Rock Drills on the Job and Out of the Repair Shop

MANUFACTURERS always have realized that the very nature of the work of a rock drill required that it be made to withstand rough service and consequently have made durability one of the prime essentials of all types. Nevertheless, like all other mechanical devices, it requires proper operation and occasional lubrication, inspection and repair.

The trouble records of one of the largest rock-drill manufacturers disclose the fact that most troubles result from improper repair and assembly after the drill has been taken apart. Some of this difficulty is due to poor workmanship in the repair shop and some of it is due to careless tinkering and repair of the drill while on the job. In any event it is mostly attributable to a lack of understanding of the importance of each part on the successful functioning of the drill.

REPAIR MAN NOT ALWAYS AT FAULT

Trouble often may be traced to the condition of the drill when sent back on the job after repair, and in many cases to the condition of the drill steel. The repair man is not always at fault, for often the operator—unknown and against the rules of most companies—will take a drill apart on the job, with the result that dirt is included in the assemblage, and the side rods are pulled up unevenly. This condition results in excessive wear of the parts, decreased power and broken through bolts.

Very often the operator complains of loss of power and decrease of drilling speed. The drill apparently works well enough, but the results are lacking. The service man's attention in this case is directed to the condition of the steel. If the bits are holding up and are of proper gage, the trouble usually can be found in the shank being of improper length or the drill socket not being fully opened. If these conditions are found to be satisfactory the trouble is looked for inside the drill. If the

Fig. 1—Properly Shaped Drill End

To get the full force of the striking piston it is important that the drill end be accurately squared off. Do not rely on guess work, use accurate tools.

piston is badly cupped or short, the power of the blow is not fully transmitted to the steel but is taken up by the front head through rods and springs.

A large part of drill trouble can be traced, especially where hand sharpening of drill steel is employed, to the size of bits used. Often the bits are too large, thereby cutting more rock than necessary, and also they are not of uniform gage. The non-uniformity of gage results in steels being wedged, excessive torque on the rotation parts and a boring or reaming operation in the rock instead of a cutting operation. Unbalanced or poorly made bits often result in rifled holes.

Fig. 2—Piston Face Must Be Square Also

If the piston becomes slightly cup shaped on the striking end and a drill with a good square shank is used, the striking edge of the piston will chip off. The striking surface of the piston should therefore be ground off square and maintained in this condition.

Where the cuttings are not properly blown from the hole, they form a cushion on the bottom and the energy of the drill is expended in cutting and recutting these loose particles instead of cutting new rock with each blow of the hammer.

Concerted efforts are being made by rock-drill manufacturers all over the country to emphasize the importance of lubrication and to introduce the proper methods of applying lubricants.

Many operators rely on the all too prevalent method of lubrication through the inlet hose. This practice should be discouraged as quickly as possible, for it is not dependable and cannot supply a continuous supply of oil to the various parts of the drill. If lubricated often enough—say every few minutes—this method would prove satisfactory. It is usual, however, to introduce a few spoonfuls of grease at the time the

hose is connected to the drill, then run the drill until it no longer operates.

Lubricators and grease pockets provided in each machine are ample to afford continuous lubrication to all parts of the drill if they are kept filled with the proper grade of lubricant.

Important points to be emphasized to obtain the best service from drills may be outlined as follows:

Fig. 3—Battered Drill Shank

Chips off the damaged drill end may become lodged in such a position that the drill will stick.

Lubrication.—See that all moving parts are always well lubricated with the proper grade of grease, as recommended by the manufacturer. It is good practice to fill the grease pockets twice each shift, as it guards against wear, increases the drilling speed and also the life of the machine.

Steels.—Be sure the drill steel is of the best quality and suitable for hard usage. See that the shanks and bits are properly made and of correct dimensions. Also give the steel the proper heat treatment, for more good drill steel is condemned and discarded because of careless, inaccurate heat treating than for any other reason. The proper heat treatment for any grade drill steel can be obtained from the drill steel manufacturer.

Air.—Know that your air supply is plentiful. Be sure that pressure at the drill is sufficient to operate it to the best advantage. Too low air pressure will decrease the drilling speed of any drill, so an examination of the air line may eliminate such trouble.

Worn Parts.—It is good practice, even when a drill seems to be giving the best of service, to take it apart occasionally and clean the parts. Wash with kerosene and examine carefully for any wear, oil all parts and reassemble. Most drill manufacturers supply limit gages which indicate when a part is worn to the point for replacing. This inspection and care will greatly increase the life of the drill.

Physical Characteristics of Insulating Varnishes

To meet adequately the many requirements of the electrical industry, insulating varnishes having widely different physical characteristics are necessary. It has not been possible to develop standard tests by which these physical qualities could be definitely measured, which makes it necessary for the user to supplement the standard tests by others to determine whether the physical characteristics are suitable for his purpose.

Generally, these tests are a practical application of the varnish to the apparatus for which it is being selected. If intended for use in making varnished cambric, the important physical characteristics would be elasticity and flexibility. The varnish could be applied to cloth and these characteristics noted. The ability of the varnish to withstand stretching without cracking could be determined by using bias-cut strips of treated cloth.

ACTUAL APPLICATION IS BEST TEST

For use on small high-speed armatures, where toughness and binding and cementing qualities are most essential, the best test, of course, is actual application to the apparatus, but this characteristic can be observed also by cutting or tearing a film of the varnish. For large form-wound coils, particularly those which may be held in stock a considerable time before use, a plastic type varnish generally is used. The varnish should soften slightly when heated, in order that the coils can be formed to exact dimensions, and be flexible, so that they can be readily assembled in the slots.

Only a few of the many uses of insulating varnish with the necessary qualities have been suggested. There are numerous others that require various combinations of qualities and each case will have to be considered individually, and the characteristics of the varnish studied with reference to the requirements of the apparatus on which it is to be used.

These tests that have been passed in review will give some general idea of the choice of varnishes to meet the many requirements of the electrical industry. Most users, by a slight change in their processes, could employ one of a number of varnishes successfully, especially if they would give a little thought to the test results and comparisons. This is, of course, difficult without a basis of evaluation.

VALUE OF STANDARD TESTS

The standard tests are of great value to both producers and users of insulating varnish, affording a common basis for discussion of the characteristics and merits of such materials. The tests of the liquid material indicate the approximate composition, relative value and general working characteristics of the varnish. The tests of the hardened films indicate the electrical characteristics and resistance to the various destructive agents.

These tests should be supplemented by other tests, preferably the actual application of the varnish to the apparatus on which it is to be used, to

verify the suitability of the varnish for the purpose intended.

Qualities as measured by the standardized tests may be made the basis of specifications for varnishes.

Would Use Fiber-Duct Where Conductors Heat Up

In regard to the article by B. K. Shaner, assistant electrical engineer, Frackville, Pa., in which he requests tables regarding the heating of conductors in iron conduits, I regret to state that I have been unable to find anything on the heating of conduits. But if it is an actual problem that he describes I think this trouble is caused by using too small wire.

One table on the carrying capacities of wires gives 3/0 for 200 amp. at 440 volts. Another gives 200,000 cm., and with rough figuring I arrived at the size of 2/0 for 200 amp. These figures do not take voltage drop into consideration. For slow-burning wire the capacity could be increased about 15 per cent, and if the conditions are dry and warm I believe this would be the best insulation to use.

It seems to me that if the power factor of the load is low abnormal heating quickly results. If the load is a meter load I would think that the power factor would be about 80 per cent. If Mr. Shaner has not installed the conduit I would like to suggest using fiber-duct as I believe it would be more suitable. At one large mine that I know of about two miles of fiber-duct is giving good service. It is encased in cement, however.

GRADY H. EMERSON,
Birmingham, Ala.

An Experience in Sickness Of Copper

An armature was being wound with coils having German silver resistance leads, with copper tips brazed onto their ends. A number of coils had been put in place when it was found that the first one had to be removed. In

doing this, the copper tips were bent back to get them out of the way. With only a single bend one of the tips broke off in the workman's hands. On examining all the tips of the coils, twelve more defective ones were found. At first it was thought that it was a bad lot of copper. Tests showed that the copper from which the tips were made was of good quality. A study of the process of handling the copper revealed that the defective tips had been heated in a flame containing unburned hydrogen.

Since one cannot see, without breaking the strap or wire, whether the copper has been affected by this sickness, it follows that to be safe copper should not be heated in a flame containing an excess of hydrogen. This means that with a blow torch the copper should be kept outside of the inner cone of blue flame. When heating copper in a gas and air furnace, an excess amount of air always should be used, as too little air will produce an excess of free hydrogen. Smoke from such a furnace always indicates too little air and the mixer should be adjusted to give a little more air than is necessary to prevent any trace of smoke. Wherever possible the copper should be heated without coming into direct contact with the flame.

Elevated Track Aids in Repair Of Mine Cars

In the car-repair shops at the Lynch mines of the United States Coal & Coke Co. one of the efficiencies of the Ford automobile factories has been adopted to facilitate repairs of mine cars. A mine track elevated on bents runs through each shop. The cars to be repaired are pulled up an incline by a small hoist and rope to the top of the elevated track. In this position the workmen can more efficiently replace or adjust mine-car riggings. Especially is such an arrangement advantageous at Lynch, where a low, wide mine car only 22 in. above the rail is used. As the illustration shows, this type of mine car is constructed so that its body overhangs and partly covers its truck.

At Lynch Mine Cars Are Put on Elevated Track for Repair

Problems In Underground Management

Proper Air Spaces Help Bring Down All Coal Undercut, Saving Coal and Powder

By Using a Small Dummy That Does Not Fill the Hole
the Pressure of Gas Is Spread Over the Whole
Length of Undermined Coal

BY W. J. GERMAN
Technical Representative
E. I. du Pont de Nemours & Co.

IMPROPER methods of loading and tamping shotholes often cause the coal to break improperly. In mines where the coal seam is only 3 to 4 ft. thick and the cuts are put in 8 to 9 ft. deep and where caps and fuse are used, coal usually is shot too hard. I have visited hundreds of miners at their working places in such mines and have found that they shoot the coal as follows:

They bore the hole, prepare the primer for the breaker shot with a short fuse, place two sticks of explosive at the back of the hole, set the primer stick in the mouth of the opening, light the short fuse and shove it back to meet the other two sticks. Then they ram in a short dummy not longer than 10 in. on top of the charge. When these three sticks explode, the coal breaks down just under the charge and most of the explosive force is lost.

This loss is unavoidable with the method of loading described because the explosive force naturally follows the line of least resistance. As there are only about 36 in. of coal under the charge, the explosion breaks the coal down at the back of the cut, and most of the gases from the explosive pass out by this channel. This leaves the face of the coal still standing so that the miner must dig it out with his pick. He does not enjoy this labor and determines to avoid it on the next cut by putting in another stick or two of

explosive—as a consequence the coal resulting from this shot is almost all pulverized.

This waste of explosives and pulverizing of the coal can be prevented by

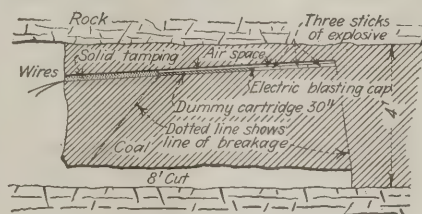

Fig. 2—A Better Way of Loading the Hole

In this instance the hole is not tightly filled for nearly 5 ft. of its length. The gases bear on the whole area undercut and all the coal falls. The same result would be obtained by using more powder but it would cost more and damage the coal more. It might also cause a dust explosion. Why use explosive when clay allows the work to be done better, safer and cheaper?

using electric blasting caps and a different method of tamping. The desired number of cartridges should be placed in the mouth of the hole, end to end, with the primer containing the electric blasting cap last, and then the entire charge should be pushed to the back of the hole.

Next a dummy of tamping about 1½ in. in diameter and 30 in. long should be shoved into the hole until it meets the charge. Finally the hole should be tamped solidly from the outside end of this long dummy to the mouth. As shown in Fig. 2 this method of tamping will leave an air space around both the charge and the dummy and this will permit the distribution of the explosive force. The gases from the explosive will spread through the coal and break up a much larger portion of it than in the first loading described and without pulverizing the coal. There is a saving in explosives and the coal is in better condition.

This method of confining the explosive charge is the most satisfactory way to balance the shot where the depth of the cut is twice as great as the thickness of the coal. It also gives excellent

results in thick seams where the coal is cut in the center, leaving two thin benches of coal to be blasted.

Keep Moisture from Telephones

BY GEORGE EDWARDS
Pikeville, Ky.

Many mines have continual trouble with their underground telephones, on the interior of which moisture is always condensing. Some superintendents have met this difficulty by placing a 25-watt electric incandescent lamp with a short globe at the back of the telephone box inclosing it in a small box of its own with five holes drilled in the two sides ½ in. in diameter. This insures ample ventilation, absence of excessive heat and uniform temperature.

Of course, if the telephone box is absolutely tight this is not necessary, but many mine telephones are not so carefully warded against dampness. It is not well to tamper with the telephone box except as a last resort.

Another plan that has given good service in damp mines is to place the telephone in a larger box with a tight door and two incandescent electric globes on each side of the telephone. This plan works well unless some careless workman leaves the door open.

More About Eyestrain and Nystagmus

Writing in the *Colliery Guardian*, D. W. Rees discussed the use of special tinted glasses to reduce the eyestrain of miners, saying that "eyestrain is recognized as causing fatigue of the nervous system, ultimately ending in nystagmus." He says that metallic-filament lamps, especially those that are gas-filled, give an intensely bright light, a considerable part of which consists of ultra-violet rays, which are recognized as being harmful to the eyesight.

He recommends tinting the glass preferably a yellowish green or, better yet, a yellowish brown. The most efficient antidote to the ultra-violet rays is at the other end of the spectrum, but a penalty must be paid in the form of greater loss of light. Protection against the excessive radiance of searchlights during the war was achieved by the use of veils and net gloves of the exact tint of sunburn, and undoubtedly this tint is the most protective against the chemical action of ultra-violet rays. To compensate for the loss of light Mr. Rees recommends using some type of prismatic glass to focus the light.

Fig. 1—Unsatisfactory Way of Loading Drillhole in Thin Seams

The gases are held in by the tamping so that they can press only on the coal around the cartridges. Consequently the end of the shothole blows the rear of the undercut coal down, leaving the front part of the undercut for the miner to handle with his pick.

Discussion

French Operators Aid Their Miners And Repair Devastated Plants

Parental Relation Between Employer and Employee—Interest Shown in
Workers' Families—Repair of Shafts Destroyed by Germans—
Craft of Latter in Work of Destruction

BY GODFREY M. S. TAIT*
Consulting Engineer, Washington, D. C.

I read with interest the article appearing in your Jan. 10 issue by John T. Ryan entitled "What American Coal Mining May Learn from European Mines," for when the armistice was declared I found myself located in the devastated northwestern coal fields of France and was shortly thereafter assigned to the preparation of a report on which the Allied Governments might base their decision as to the reparations to be demanded.

I, therefore, take the liberty of corroborating and supplementing Mr. Ryan's remarks as to French mining equipment and as to the satisfactory relations existing between employers and employees.

For example, on the subject of pay: In the Marles section the underground men averaged 7½ fr. per day and day men 5½ fr. in 1913. In the Noeux section the underground men received 7 fr. and surface and day laborers 5 fr.

In 1918, however, wages had jumped tremendously, due to the shrinkage in value of the franc and to the general high cost of living, so that at Marles the wages were 15 fr. and 12½ fr., respectively, for the two types of labor, whereas at Noeux they were 16½ and 9½ fr., respectively.

This, as Mr. Ryan writes, has been reduced down to the basis to which he refers, but it is interesting to note that there is no standardization between the wages paid at adjacent collieries. In some cases the discrepancy in wage is as much as 2 fr.

This is largely, if not entirely, due to the fact that the workers in these French mines have such a genuine affection for their employers, whom they almost regard in the light of parents, that it is almost unknown for the workers in one "concession" to be influenced to go to work in another.

I talked to hundreds of these returned workers and they all left me with the same impression, namely that the place at which they worked was their home. There they were provided with a comfortable little brick house with a tiled roof and with sufficient space in which to grow vegetables for the family. They would not think of leaving that particular concession any

more than they would think of abandoning their own homes. In fact I suggested at that time that they would be much better off if the French were to occupy the Ruhr and move them up there far from the devastated areas, but they unanimously replied "No, no, M'sieur, that would not be France."

I have seen these miners, who had been driven into Paris during the war, tramping along the 65 miles of road pushing their belongings in wheelbarrows and little carts, and arriving at the ruins of what had once been their home, with no apparent possibility of operations being resumed for years, but still looking completely happy at being "home" once more.

Each mining concession was equipped with a large hospital with a free clinic for the care and nourishment of children; the companies usually made it a practice to give a salary bonus of a few francs per week for each child in each family under sixteen years of age (thus undoubtedly showing a farsighted labor judgment); when children were born to the families of miners the minor expenses were paid by the company; when they entered the church they usually received some little gift; when they married they usually were given something more substantial and probably a house to live in; and when they died the company buried them in the concession churchyard, where you might see, before the Germans destroyed them, the headstones of generations of French miners, giving mute

proof of the stability of the local class of labor.

The country is rather flat and has a fairly rich soil, much beet sugar being grown in that section. Before the war the well-paved roads which stretched away to the horizon usually were shaded by two rows of giant poplar trees, the average thickness at the butt being over 2 ft.

As Mr. Ryan says, this territory was captured in the early stages of the fight, and the Germans took full measure of the facilities offered. All trees were leveled so as to prevent the approach of the enemy unseen; the slate piles, which because of the type of mining were of enormous size, were tunneled and timbered with posts and caps from the company's stockpile. Thus converted to their use the Germans employed them as observation posts and gun emplacements.

The network of railroads was torn up and cut into short lengths for reinforcement in concrete dugouts, and three companies of pioneers of seventy men each made an extensive study as to means for the future destruction of this industry in the event that they could not hold the country against the French.

The buildings employed were almost universally steel structures and every girder and column was marked by the Germans with the number of grams of powder that would be required to destroy it. When the order for retreat was sounded only a few days before the armistice the hoists were loaded with TNT and lowered in the shafts to an average depth of 300 ft., at which point they were opposite the water strata, which in this section appears to be in connection with the ocean. The charge was then fired, tearing a hole in the side of the shaft lining, through which the water poured in a river falling to a depth of from three to four thousand feet, as the case might be.

The underground workings around Lens were all flooded in this manner, but the same treatment was not accorded other mines as in the rapidity of retreat it is generally considered sufficient to destroy the surface plants, and this was done in the following manner:

Top Works of Dechy as Germans Vacated Them

This is not the result of gunfire but of a carefully planned and executed devastation warranted to make reconstruction as difficult as possible. The dimensions of the big conical winding drum can be gaged from the size of the men standing nearby. The shaft is over 3,000 ft. deep.

*Late Captain C.W.S., American Expeditionary Force.

A small charge was placed on the surface of each steam and air cylinder of each engine. A charge was attached to the steam dome of each steam boiler. The supports of the breakers were shot off so as to drop the buildings 5 or 6 ft., thus preventing cars going underneath to take coal and throwing all the shaker screens out of alignment. Finally the giant headframes were destroyed by blowing two legs out from under them, allowing the monster frame to crush through the roof of the power house. I have about two hundred photographs which I took of this type of devastation and the uniformity of method employed is striking.

It is impossible to overrate the courage and ability with which the French restored these mines to production. According to my estimate at the time I figured that it would take ten years to repair the damage, provided abundant financial assistance and a supply of new equipment was forthcoming. As you know, there has been no financial assistance other than that from French pockets, and, due to the shrinkage in value of the franc, little machinery was ordered from abroad.

With regard to the water in the mines at the time of my inspection, reference to my notebook indicates that it was estimated at 100,000,000 cu.yd. and that at the cost of labor then obtaining it could be removed for approximately 70,000,000 fr. I see also among my notes the remark, "The reason that the dewatering cannot proceed at a greater rate than planned is that the flow of water through the underground workings must be kept within moderate limits; otherwise erosion would occur sufficient to displace the foundations of some of the timbers, and one bad slip in mines such as these might seriously damage the entire property. Furthermore, the roof usually encountered is none of the best and unwatering should be accompanied by constant inspection and the replacement of mine props and the installation of new timbers where needed."

TIMBERS AND TREES DESTROYED

In this connection it is interesting to know that the Germans removed or destroyed not only the entire supply of mine props and timbers but cut down and destroyed every tree in that part of the country. Perhaps it may seem to you in reading this that the description of the thoroughness with which the Germans completed their destruction of this great coal field is all out of reason and that no intelligent race would go to the scientific lengths shown in this case for what appeared to be purely vindictive reasons. As to this, I think you will find the explanation in the closing paragraph of my report on this devastated area, which is as follows:

"But the loss to France is far more serious than the mere money value of the coal, as will be apparent when France's steel industry and resources are considered.

"Previous to the war France mined more iron ore than, for want of fuel, she

A Little of the Destruction Wrought by Germans at Notre Dame Colliery

The buildings employed at the Collieries of northern France were almost universally steel structures, and the Germans carefully marked each girder and column with the number of grams that would be needed for its destruction. This illustration shows what happened when the directions were followed.

was able to fabricate. In fact, she was dependent on German and Belgian coke in a large measure. Her surplus iron ore naturally had to be sold to Germany, where in the Somme and Ruhr basins coke was abundant. This situation gave Germany a strong hold at all times on France's steel industry. The strength of this economic domination is in inverse proportion to France's coking coal production, hence any decrease in French coal production correspondingly lowers the value of her iron ore and the volume of her steel production, her only resources being to sell unfabricated iron ore to the German steel works in the Ruhr at their own price.

"This was the reason for the deliberate, systematic and scientific destruction of the French coal mines. It will further be noted that no great damage was done to France's iron mines, although her steel works were utterly destroyed. Germany wants the French iron ore, and failing to hold the property by military means she has created an industrial condition which accomplishes the same purpose."

At this point it may be well to stop and realize just why France seized the Ruhr when she failed to obtain any reparation to apply to the restoration of what was the Ruhr's only business rival.

I note in Mr. Ryan's article that 140 of the mining shafts were destroyed by dynamite in the method which I have recounted above. I have photographs to prove that miners' houses even more substantial and attractive than the ones shown in this article also were totally destroyed, the usual German trick being to throw a hand grenade in the cook stove as a parting shot.

It may be of interest to you to know how the French succeeded in repairing these damaged shafts. Their process strikes me as being so highly ingenious that I never fail to relate it.

When I told you that I had located many shafts by the roar of the water entering them and by observing the

cloud of spray that rose up into the air above them, you can have a faint idea of the mechanical difficulty of checking this flow before complete flooding was accomplished.

However the French engineers are never lacking in resourcefulness, and the method they employed was really exceedingly simple. They first of all erected a temporary headframe to carry the centrifugal pump with which they expected to dewater the mine. Then from this same headframe they lowered what may be described as a caisson consisting of vertical strips of wood like a straight-sided barrel, this structure had a slightly smaller diameter than the circular shaft. This was lowered until it covered the opening through which the water was entering.

Then by means of jacks suitably arranged in the center of this caisson it was expanded until its ribs fitted tightly against the side of the shaft. In thus expanding the caisson the ribs, of course, moved further apart leaving plenty of space for water to continue to enter. These slots were then calked until all leakage ceased.

This left the shaft with the damage stopped, but the shaft itself useless, due to the presence of this caisson which filled the opening. The next step was to drill small holes through the wooden caisson into the water space, to introduce pipes through these holes, and to pump in a dry concrete mixture which in coming into contact with the water gradually formed a solid cement which fitted tightly against the exposed side of the caisson. After the cement had time to set, the jacks were released and the caisson hoisted out of the shaft, the repair in which presented a perfectly smooth surface.

It is needless to say that seams of coal presenting the same mining difficulties as those in France would be considered absolutely worthless in this country, but with the economic situation existing in France it is difficult to estimate the value of such a natural resource to her.

Production And the Market

Soft-Coal Market Shows Strengthening Trend; Consumer Evinces Scant Interest in Wage Parley

Strengthening tendencies are apparent in the soft-coal market. More seasonable weather has increased the demand for domestic bituminous coals and some industrial concerns in Ohio and other sections are adding to their reserve stocks at the present low prices. The Jacksonville meeting does not appear to be attracting much attention from the consumer, and there is a feeling that no serious trouble will be encountered. Those mines that are working in most instances are operating to capacity and some producers are getting ready to open additional operations to meet the demands, but in some cases they are finding it difficult to obtain men.

Contract making is progressing slowly, but the range of prices appears to be from \$2.25 to \$3.25, as compared with \$2.75 to \$4.25 last year.

No Reason Seen for Drop in Output

Production of soft coal during the week ended Feb. 2 declined slightly when compared with the previous week, though no reason is apparent. On the other hand, the output of anthracite shows an increase, although the demand for domestic coals usually present at this season is lacking. Demand for soft coal had been quickened because of the low temperatures and there are fewer reports of "no market" losses.

Comparatively few changes in prices are reported from the various markets, with the result that *Coal Age* Index as of Feb. 11 stands at 188, an increase of one point, with an average price of \$2.27, also an advance of 1c. from the previous week.

In the Middle West the domestic trade has slowed down, due in part to difficult hauling from the retail yards and a letting up in the severe cold weather that struck that section of the country a couple of weeks ago.

The lower temperatures enabled producers to move their "no bills," but there still remains a large number in southern Illinois. The St. Louis trade in domestic soft coals is active, but anthracite, smokeless coals and coke move slowly. Eastern Kentucky coals are pretty well sold up for the present and the market is slightly firmer. Milwaukee reports a very active market, with business at its peak. Practically similar conditions exist over the Southwest, a blizzard interfering with mine operations early last week.

Active Markets Reported in Ohio

The Ohio markets generally report activity. Smokeless coals are in good demand and deliveries are lower due to a cut down in car supply on one railroad. Free coals are pretty well taken up for the time being, and splint and gas coals show more strength. Steam coals are in fair demand, but with large consumers holding fair reserves there is no tendency to add to them. There is a moderately active market at Pittsburgh, the greatest interest being shown in what will take place at Jacksonville. In New England there is little encouragement in the steam-coal situation and practically no change in the market for Pennsylvania coals. The New York, Philadelphia and Baltimore markets are quiet. There is no activity and buyers of spot coals are taking only enough for immediate needs. Inquiries show no increase.

Output of soft coal for the week ended Feb. 2 was 11,315,000 net tons, a decrease of 254,000 tons when compared with the previous week, according to the Geological Survey, while 1,893,000 net tons of anthracite was produced, as compared with 1,782,000 tons during the week ended Jan. 26.

During January of this year fourteen steamers left

Calendar year	1,600,000	1,240,000

(a) Subject to revision. (b) Revised from last report.

Baltimore carrying 70,225 tons of coal to foreign countries, and one vessel carried 3,491 tons of coke. In January of last year the sailings were three vessels carrying 4,119 tons of coal. Dumpings at Hampton Roads for all accountants during the week ended Feb. 7 totaled 369,171 net tons of coal as compared with 283,447 tons during the previous week.

Midwest Markets Quiet

Trade in domestic coals has slowed down throughout the Middle West. This may be partly due to the difficulty retailers have in moving coal out of their snowbound yards. The call is fair but is not expected to pick up much from now on unless another spell of severely cold weather comes. This means the production of the region is falling and screenings are due for a rise. Not much stiffening on steam coal is noticeable yet, however.

The recent blizzards enabled producers to move out most of the "no bills," but there still remain a good many in southern Illinois loaded with the middle sizes. Central Illinois is less afflicted because of its proximity to the

great Chicago market. It has sold about all of its production readily, but at fairly low prices. Screenings range now from \$1.25 to \$1.35 and lump is \$3@3.25.

In the Illinois mining fields the southern counties are getting from two to four days a week. Railroad tonnage is light.

Conditions in the DuQuoin and Jackson County field are somewhat similar, with the prices matching those of the independent Franklin County operators. The business in this district, however, is not good and steam coal is difficult to move. The Mt. Olive situation is better. The demand for domestic is good and steam is fairly active, but there is a car shortage that interferes with production at times. In the Standard district the last short cold wave helped conditions materially, although there is plenty of coal of all sizes that has been piled up for the last week at the mines. Steam is hard to move and screenings are down to 75c.@80c.

St. Louis Trade Still Alive

Dealers in St. Louis report local domestic trade active and the demand for middle grade coals good principally on account of the cold wave. Some high-grade lump is moving, but it is small in comparison with middle grades, and

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

	1924		1923	
	Feb. 11	Feb. 4	Jan. 28	Feb. 12
Index	188	187	187	296
Weighted average price	\$2.27	\$2.26	\$2.26	\$3.58

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

there is some activity in Standard. Anthracite, smokeless and coke are slow. Wagonload steam showed considerable improvement the last few days. Country domestic is doing well. It dropped off for a few days, but it is coming back for cheaper coals principally. Country steam is soft and in no demand.

Kentucky Moves Much Lump

Over the past week there has been some advance in eastern Kentucky coal due to the fact that a good many operators are sold up for the time being and are quoting high, whether getting business or not, which has a tendency to firm up the market a little. There has been a better demand for gas or byproduct coal, which is beginning to carry a larger premium over non-gas varieties. There also is a better steam business from the North, and good scattered retailer demand from almost all sections.

Eastern Kentucky mine prices have been firmer all along the line over the past week with domestic sizes tightening up 15c. to 25c. while the western Kentucky market is about holding its own, but with prepared coal getting the call and with some houses holding for slightly higher prices.

Western Kentucky screenings have been offered more freely on the local market and at as low as 85c. for the pea and slack grade.

Demand for western Kentucky coal has been fair, but is largely for prepared coal, moving to all sections, but especially the North and Northwest, including Iowa and Michigan, Illinois and Indiana, with a good movement in Kentucky and Tennessee. Movement of prepared has increased selling effort on screenings, which have been a little off in price due to larger production. This is forcing a hard scramble for orders to keep the markets up.

A number of mines that have been down have resumed operations, making the struggle for markets quicken. The strip or daylight mines, meeting bad weather conditions, have not been able to produce coal as cheaply as under better operating conditions, which is helping the shaft operators a little.

Northwest Is Busy

Shipments from the docks at the Head-of-the-Lakes in January were higher than at any period since July, 1922. In all, 25,984 cars left the docks both at Duluth and at Superior, Wis., of which 10,189 were shipped from Duluth. The shipments last month compare with 17,215 in December and 13,683 in January of last year.

Despite the huge shipments, which are mostly on contracts and for buyers who have been shaken loose by cold weather, the price of bituminous coal dropped 25c. a ton all around at Duluth last week. This is a reduction on the prices quoted last week. All coals are affected except Pocahontas, which remains as last quoted. The strength of Pocahontas is caused by the fact that it is proving a most acceptable substitute for anthracite, which is growing scarce in desirable sizes. Stocks on docks now are probably about 4,300,000 tons.

The Milwaukee coal market is very active. The winter business is at its peak, due to widespread low-temperature blizzards. Country business is suffering because of interrupted telephone and telegraph communications and blockaded railway traffic. Coal is moving out fairly well, however. Prices are firmly held.

West Active Again

A blizzard over the Southwest early in the week prevented operation of Kansas and Oklahoma mines two or three days. As a result of the enforced idleness and the increased demand which followed the snow and colder weather, no-bills, which again had begun to accumulate, were cleared from the tracks, and mines were assured of steady operation for some time as soon as weather might permit their reopening. Prices are steady at \$5 for Kansas lump, \$4.25 for nut, \$3.50 for mine-run and \$2.25 for screenings.

The coal market in Colorado during the past week continued to remain reasonably active. Mines worked about four and one-half days, attributing only 18 per cent of the lost time to "no orders." Prices remain unchanged and the supply of labor is ample. The transportation and equipment situations have been very favorable throughout the entire state except in Routt County district (which is served only by the D. & S. L. R.R.), where approximately 94 per cent of the full working time for that district was lost on account of weather conditions preventing any transportation movement.

In Utah every shipper is short on both lump and slack, but middle sizes are piling up on operators' hands and causing a lot of grief and lost time. Retailers have been moving a good deal of coal and stocks are getting low. In Salt Lake City, for instance, the total is estimated at less than 10,000 tons. A week of zero weather would clean them out.

Conditions in Ohio Improved

Market conditions at Cincinnati are considerably improved and wholesale dealers are kept busy. Towards the middle of last week there was a rush for smokeless coals and with the New River production cut down by a 50 per cent car supply on the C. & O. and with the Pocahontas operators in the position of being sold up on their "available" coal for a couple of weeks to come, higher prices were obtainable. Low-volatile slack also moved up under the demand that was coming in from the byproduct plants. Splint and gas coals, especially the domestic sizes, were

strengthened because of the general slowing up in transportation north of the river. Demand was better due to cold weather. Block as well as mine run stiffened, while slack took a spurt. There is a feeling that the urgency of orders was due to some of the industrial centers desiring to replenish their storage supplies. For retail delivery Pocahontas lump is quoted at \$10 by a majority of the dealers, with one or two still holding to \$9. On slack the new range is \$4.75@5.

With weather conditions at Columbus unsettled the coal trade was rather spotty, with domestic buying the best feature. Retail stocks are only fair but because of the lateness of the season dealers are not buying for the future. Pocahontas and other smokeless varieties are in good demand and prices are stronger. Splints also are selling well, but lack of an adequate car supply is one of the drawbacks of the West Virginia operators. Ohio-mined coals are selling steadily and operations have increased to about 30 to 35 per cent of capacity in the southern Ohio fields. Several of the large buyers of steam coals continue to remain out of the market. Stocking is not general as most of the larger consumers have adequate stocks on hand. Contracting is at a standstill both because April 1 is the usual contract period and also because of the uncertainty of the market. Reports received by the Southern Ohio Coal Exchange show a production during the week ended Jan. 26 of 207,625 tons out of a total capacity of 677,173 tons. "No market" was responsible for a loss of 398,546 tons.

The outstanding feature of the market at Cleveland is the large volume of bituminous-coal receipts 4,323 cars having been received during the week ended Feb. 2, or 460 cars more than the preceding week and 260 cars greater than the previous high record week of Jan. 19. There is considerable distress coal on hand and some has been disposed of at 10c.@15c. below the current market quotations.

The Pittsburgh district market has been moderately active as compared with its condition in December. Competition is very keen and the outlying non-union mines are receiving the chief benefit of any increase in buying. There was an improvement in buying reported in central Pennsylvania during January. Some yearly contracts are reported as having been signed on a basis of \$2.40 for the medium grades and \$2.80 for the better grades of coal. There is a little more activity in the Buffalo market.

New England Steam-Coal Market Dull

The market for steam coal continues to offer little encouragement. Production in the smokeless districts has increased and because there is nothing in the current situation to support a larger tonnage the range of spot prices has suffered another decline. Navy standard Pocahontas and New River can now be had at \$4.75@4.90, a drop of at least 15c. from a week ago. Operators are anxious to net \$2 per net ton at the mines, but occasionally a lower return is accepted in order to free cars and make room for further shipments. In this territory there is next to no inquiry and efforts to interest buyers in contracts so far have been without result.

All-rail there is practically no change. Producers find it hard to understand the lack of business in New England. They feel there must be some opening somewhere, but the holes are filled about as soon as made, and by coals from Hampton Roads. The industries still find it hard going, and few are optimistic over 1924 conditions.

For inland delivery there is only very light request. Quotations there, too, have eased off a little, and \$6.25 is now the utmost price sought. As it is, practically the only coal being sold is in the hands of factors with their own depots, and the tonnage is moved to make room for cargoes due to arrive.

Seaboard Soft-Coal Market More Active

There has been somewhat of a change for the better in the soft-coal market at New York but it has not been sufficient to affect prices. Buying has not increased despite the nearness of April 1 and little interest is being taken in the conferences at Jacksonville. Conditions at Philadelphia show little if any difference from those that existed last month. Inquiries are increasing and salesmen do not find it so difficult to get orders although they are not plentiful. Some extra buying is reported. The trade at Baltimore is flat and little buying is reported. Lack of demand continues at Birmingham, particularly for steam coals. Business is scattering and spot buying is for immediate needs. Dealers are buying domestic coals only as needed.

Little Activity in Anthracite Market

There is very little activity in the anthracite market. The demand centers around stove and chestnut coals, but there is no shortage of these sizes. Retail dealers are not rushed regarding deliveries and consumers are not inclined to buy heavily at this season. Egg and pea coals are hard to move, some of the producers storing large quantities of the latter size. Independent producers find it necessary to quote close to company prices in order to keep their coals moving. The steam-coal situation has improved and demand is stronger. The better grades of independent barley coal are being quoted at figures above the company price of \$3.50. Dealers at Baltimore are not complaining of supplies; in addition to receipts of Pennsylvania anthracite they received about 8,000 tons of Welsh anthracite last week.

The Connellsville coke market did not experience the improvement expected a couple of weeks ago, when several inquiries were made for second-quarter furnace coke. Operators were disposed to quote 25c. advance for second quarter over what has been going for the current quarter and this seems to have caused furnace men to lose interest. The usual asking price for the second quarter is around \$4.50. The spot furnace coke market has been stiffer in the past week and is quotable at \$4@4.15. Foundry coke remains quotable around \$5@5.50 in the spot market. The Geological Survey estimates beehive coke production for the week ended Feb. 2 to have been 262,000 net tons, as compared with 263,000 tons the previous week.

The U. S. Bureau of Labor statistics from the records of U. S. Geological Survey show that on Dec. 22 32.9 per cent of the mines had not worked during the preceding week.

Foreign Market And Export News

British Coal Output Rebounds with End of Rail Strike; Orders Accumulate

Great Britain's coal output for the week ended Jan. 26 was 4,717,000 tons, according to a cable to *Coal Age*. This compares with 2,848,000 tons for the week ending Jan. 19 and 5,747,000 tons produced in the week ended Jan. 12, which was prior to the strike of the railroad men.

The railroad strike had exerted a paralyzing influence on the Welsh coal trade. Owing to the shortage of railway locomotives, coal could not be conveyed from the pits to the docks. Ships have been held up in consequence and stocks have accumulated at the pit-heads. Aside from this the market is firm and nearly all the pits are booked up until mid-February, and are not taking more orders. Business with Europe is good, except that German orders have fallen off, while Italian business has increased. South American business has improved. It is expected that when the railways have got into their stride again the Welsh market will very much improve in tone.

The Newcastle market has been hit in the same way and considerable difficulty has been experienced in getting coal to the docks for shipment. In the meantime orders have accumulated and the outlook for February is regarded as being distinctly promising.

French Coal and Coke Imports and Exports

France imported 26,268,187 tons of coal during the twelve months ended Dec. 31 as compared with 22,334,126 tons in 1922, an increase of 3,934,061 tons. Of the total Great Britain furnished 17,954,597 tons as compared with 12,098,927 tons in 1922, and the United States furnished 670,823 tons as against 23,255 tons in the previous year. Bel-

gian coal received was 2,179,099 tons, a decrease of 199,598 tons when compared with the previous twelve months. German product received was 1,478,527 tons, as compared with 3,730,605 tons in 1922, while receipts from the Sarre were 3,182,275 tons, as against 3,534,224 tons received in 1922.

Coke imports amounted to 3,628,393 tons, as compared with 5,140,183 tons in 1922, of which 2,073,460 tons was furnished by Germany. In 1922 German coke receipts amounted to 4,303,324 tons. The United States furnished 169,358 tons during 1923, Belgium, 497,839 tons; Great Britain, 384,101 tons and the Sarre, 96,431 tons.

There was exported from France during 1923 127,012 tons more of coal than in 1922, 2,274,447 tons having been shipped during 1923 as compared with 2,147,435 tons in 1922. Of this tonnage Belgium received 1,166,805 tons; Switzerland, 438,461 tons; the Sarre, 241,027 tons; and Germany, 67,740 tons. In 1922 Belgium received 453,075 tons; Switzerland, 704,048 tons; Italy, 59,022 tons; and Germany, 454,950 tons.

Of the 496,348 tons of coke exported in 1923 Italy received 269,060 tons; Switzerland, 163,318 tons; Belgium, 15,298 tons; and Germany, 2,204 tons. In 1922 463,128 tons of coke were exported, of which Italy got 192,880 tons and Switzerland 89,334 tons.

Hampton Roads Market Shows Weakness

Conditions at Hampton Roads were fair last week the market showing a tendency toward weakness, and demand dropping off in all quarters. Foreign business was a trifle more active but the prospect for overseas trade was not bright.

Coastwise and bunker trade was only

fair, and supplies of coal at tidewater were accumulating. Some inquiries for contracts were reported, although the trade generally showed less activity than during previous weeks.

Operators were intimating they would make contracts for \$2.50 net ton mines, which would mean \$5.32 at tidewater, and shippers received some inquiries for bookings at this figure.

Traffic News

Lower Rates Sought on Coal For Export

A resolution asking the Norfolk & Western, the Cheapeake & Ohio and the Virginian railroads to adjust the rates on tidewater coal destined for export to the extent of one dollar a ton, has been adopted by the Kiwanis Club, of Welch, W. Va., to the end that mines served by these roads may be in a position to compete with foreign mines for export business.

Operators join in stating that there is not a sufficient domestic demand to permit the mines in West Virginia to operate for more than one and two days a week. Export shipments have dwindled from 13,300,000 tons in 1920 to 2,900,000 tons in 1923, the shrinkage being due to the fact that the present freight rates on coal are so high that southern West Virginia producers are no longer able to compete with foreign countries.

Final Argument on Hard-Coal Joint Rate March 19

Final arguments are to be heard in Washington, March 19 before the Interstate Commerce Commission on the matter of allowing the cancellation of the joint all-rail rate from Buffalo to Minneapolis on hard coal. Stanley B. Houck, counsel for the Twin City Coal Exchange, will present an argument against allowing the withdrawal of the rate. County Attorney Floyd B. Olson, of Minneapolis, will present a brief on the case, but will not be able to attend the hearing on that date.

Illinois Towns Ask Rate Cut

Rockford, Freeport and several other Illinois towns are asking a reduction of coal freight rates to those cities from all Illinois producing groups. The Illinois Commerce Commission hearing on the petition was assigned for Chicago, Feb. 14.

Car Service Has New Quarters

It has been announced by the American Railway Association that, effective Feb. 1, the headquarters of District No. 2, Car Service Division, will be at 2025 First National Bank Building, Detroit, Mich., instead of 1219 Nicholas Building, Toledo, Ohio.

C. & O. to Repair Coal Cars

Contracts for repairing 1,000 steel coal cars have just been awarded by the C. & O. Ry., according to announcement made by W. J. Harahan, president of the company. The repairs will affect the coal trade to a considerable extent, it is stated, inasmuch as it will go far toward a prevention of car shortage should there be the anticipated appreciable revival of the coal business in the spring and summer.

Coal Rate Cut in Illinois

The Illinois Commerce Commission has instructed the Wabash R.R. to establish a rate of 70c. per ton on coal from Springfield, Ill., to Decatur, Ill., this rate comparing with 91c. per ton, the former rate, and giving Decatur one of the most favorable rates in the state. Bloomington has won a victory in its contest for lower freight rates from Lincoln, Ill., the Illinois Commerce Commission denying a rehearing in the Springfield-Lincoln-Bloomington coal rate case.

Industrial Notes

The Tennant Company, with offices in the Union National Bank Building, Houston, now represents the Heine Boiler Co., of St. Louis, in a new territorial division comprising the entire southern half of the State of Texas, J. A. Tennant being in charge of this office. Smith & Whitney of Dallas, Texas, continue as the company's representatives in the northern half of Texas.

Wheeling Coal Co., Warwood, W. Va., near Wheeling, has contracted with the Fairmont Mining Machinery Co., Fairmont, W. Va., for a complete steel tippie with shaker screens and other preparation equipment.

A method of fireproofing jute for brattice cloth has been perfected by J. A. Willard and others and the Canadian Brattice Cloth, Ltd., has been incorporated at Vancouver, B. C., to enlarge and operate a plant on False Creek for its manufacture. At present most of the brattice cloth used in western Canada comes from Scotland.

Milton W. Arrowood announces that he has purchased all the interest held in the Ground Coal Engineering Corp. by the Sanford Riley Stoker Co. since Dec. 22, 1922. The company will now be operated by Mr. Arrowood and his associates in Chicago, under the name **Universal Engineers, Inc.**, as it is believed this name will be well suited for the company's pulverized fuel work and its general line of activities in conveying and handling materials, the success of its method in handling pulverized fuel having led to expansion in other fields. Pending the establishment of offices in New York and Chicago, the company headquarters will be 2 Downing Street, Worcester, Mass.

Barnes & Tucker Co., of Barnesboro, Pa., has ordered from the Fairmont Mining Machinery Co., Fairmont, W. Va., a steel tippie and preparation equipment.

A state charter has been issued to the Summerville Mine Supply Co., Summerville, Pa., the purpose of which is to buy, sell, and deal in coal-mine equipment and machinery. The capital stock of the company is \$15,000 and the incorporators are: Ira B. Brocius, Summerville, treasurer; S. R. Madill, Summerville, and George A. Getty, Summerville.

Association Activities

At the January meeting of the **Smokeless Coal Operators Association of West Virginia** held in Washington, Major W. P. Tams, Jr., of Tams, second vice president of the association presided. President Robert H. Gross, of Boston, having been seriously ill for the last six or seven weeks and William C. Atwater, of New York, president of the William C. Atwater Co., being abroad.

The association accepted with regret the resignation of George R. Collins of Charleston as treasurer of the association. Mr. Collins retires owing to ill health. G. H. Caperton, of Charleston, was elected to succeed him as secretary. Mr. Collins also

resigned as a member of the board of governors representing the Tug River district, John T. Wilson of Bluefield being elected in his stead.

The association gave much of its time to reports from transportation committees with special reference to the present status of the effort to obtain an all-rail through freight rate from the smokeless fields of West Virginia to the Middle Atlantic and New England states. Attention also was given to the preparation of defending West Virginia's interests in the coming fight on freight rates west, as a part of which operators of the Pittsburgh fields are endeavoring to widen the present freight rate differentials against West Virginia in favor of operators of Pennsylvania. The Faith Smokeless Coal Co. and the Morrison Coal Co., both of Glenn Morrison, Wyoming County, were admitted to membership.

Late in January the **Greenbrier Smokeless Coal Operators Association** held a session at the Kanawha Hotel, in Charleston, when routine matters and conditions generally affecting the industry were discussed. The following were in attendance: W. S. Wood, Quin Morton, D. C. Kennedy, H. H. Blackburn, John B. Laing, James Laing, Mason Bell, E. S. Simpson, J. G. Hood, W. M. Jasper, O. M. Richardson, J. N. Turner, W. H. Naylor, Dr. J. Y. Leach, J. Wade Bell, H. S. Wilson, Robert T. Bell and W. G. Crichton.

At the last meeting of the **Clarksburg Coal Club** discussion revolved about the possibility, upon the expiration of the present wage contract, of an adjustment in scale rates in the Harrison County field which would give the territory an opportunity to compete with other fields. Increases in freight rates and inability to reach certain markets, it was developed during the meeting, have precluded the production of a larger tonnage of coal in the Harrison County field within the last year. The operators at the meeting also discussed developments at the convention of United Mine Workers and matters affecting the local field. Hugh G. Smith, president of the club, presided at the meeting. It was stated by operators that despite the large production in West Virginia during 1923, amounting to over 103,000,000 tons, Harrison County had contributed a much smaller proportion to the total than usual.

They were frisky in their announcements of the meeting of the **Rocky Mountain Coal Mining Institute** at Denver Feb. 13-15. A large yellow circus-looking handbill announced "Last and final notice! Three days of mental food, with a strong seasoning of fun. Girls! Girls! Girls! Lots of 'em. Wives, daughters, sweathearts. Bring 'em with you. We'll do the rest. Unparalleled announcement! George B. Pryde positively will be with us in person. Whales and Elephants. All the heavyweights of the industry will be there to see Bill Brennan on the flying trapeze. He positively will not perform. So come and join the fun. Denver Hotel rates will not be raised." Ben Shubart is secretary and conceived this whizzical notice which was decorated with various sketches and about all the different faces of type the print shop could exhumate from its mustiest racks.

Charles Dering, president of the **American Wholesale Coal Association**, has designated the following committee to take charge of arrangements for the Association's annual convention: Jay W. Johns, Pittsburgh, chairman; J. A. Collette, Pittsburgh, and G. H. Merryweather, Chicago. The convention will be held at White Sulphur Springs, W. Va., June 3 and 4.

Coming Meetings

American Institute of Mining and Metallurgical Engineers. Annual meeting Feb. 18-21, 29 West 39th Street, New York City. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

Upper Potomac Coal Association. Annual meeting March 3, Cumberland, Md. Secretary, J. F. Palmer, Cumberland, Md.

Canadian Institute of Mining and Metallurgy. Annual meeting March 5-7, King Edward Hotel, Toronto, Ontario, Canada. Secretary, G. C. Mackenzie, Drummond Building, Montreal, Quebec, Canada.

New England Coal Dealers' Association. Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.

Northwestern Pennsylvania Coal Operators' Association. Annual meeting March 4, Butler, Pa. Secretary, T. F. Diefenderfer, Butler, Pa.

News Items From Field and Trade

ARKANSAS

Sale of the Arkansas Anthracite Coal & Land Co.'s property at Clarksville, made in accordance with decree of the court, has been confirmed by Federal Judge Frank A. Youmans. The sale was made by H. Denman, receiver, to R. A. Blackwood, who bid \$99,000.

ILLINOIS

Affairs of the Southern Gem Coal Corporation have come to a grand pause for the time being. The company, now in the hands of W. S. Wilson and Judge C. B. Thomas, of East St. Louis, as receivers, has not produced a pound of coal since an eight days' run under the direction of Judge Thomas and Mr. Wilson late in January. The books are now being audited to learn the exact status of the concern. The offices soon will be moved to Pinckneyville, leaving only a sales office in Chicago. An effort is to be made to reopen the mines soon. Jesse Dimond and John M. Dillavou have left the company, but Chester A. Harris continues as vice-president. The directors have elected D. M. Parkhill, of Benton, to be president and secretary, H. M. Rea as treasurer. The status of Simon Levy's "snowbird" contract for the entire output of two Franklin County mines of the corporation is in doubt. Thus far Mr. Levy has received nearly \$100,000 worth of coal.

Charles F. Schrage, for years vice-president and treasurer of the Peabody Coal Co. of Chicago, is withdrawing from his connection with the company. **Walter A. Fisher**, assistant treasurer, succeeds him, although no official announcement has yet been made.

Officers for the Chicago Collieries Co., Danville, have been named as follows: Ben B. Taylor, president; T. C. Keller, vice-president; William Dolan, treasurer; C. E. Parker, secretary. These men, with Joseph Meitzler, A. Plaut and T. T. Keller compose the board of directors. The election was held at Catlin. **The Taylor-English Co. elected the following officers:** Ben B. Taylor, president; William Dolan, treasurer, and H. E. Douglas, secretary. These men, with George Meiser, Ft. Wayne, Ind.; Clarence Davis, Danville, Ill., and T. A. Taylor, Catlin, Ill., compose the board of directors. The Chicago Collieries Co. which absorbed the Lone Oak Coal Co. Jan. 1, has changed the name of the Lone Oak mine to the Chicago Collieries No. 3 and expects to have 300 men employed this season.

E. J. Gibson of Danville, has been elected president of the **White, Barger, White Coal Mining Co.** of that city. The company has been reorganized, Mr. Gibson purchasing 51 per cent of the stock of the company. The new organization will continue operations on the property, south of Danville, on the Chicago & Eastern Illinois R.R., and has obtained options on 80 acres more, where stripping operations will be continued. Negotiations are pending with Indianapolis parties for purchase of the property. The company was incorporated five years ago for \$100,000.

The Illinois Fuel Co. was awarded judgment for \$51,811.48 by Circuit Judge Hugo Grimm, of St. Louis, Feb. 5 in its suit against the Mobile & Ohio R.R. A jury trial was waived. The suit was based on a contract for 50,000 tons of mine-run coal at \$2.45 a ton subject to readjustment of price under certain circumstances. The coal company claimed \$125,126.77 under the contract of which the railroad had paid \$68,954.02.

INDIANA

Two hundred miners who have been employed on day and night shifts at **Francisco Mine No. 2**, four miles west of Princeton, will be idle for several weeks, it has been announced. The shutdown is due to fire inside the mines which is believed to have been caused by defective wiring. Mine officials have sealed the mine in order to suffocate the fire from want of oxygen.

The Dugger Mutual Coal & Mining Co., of Dugger, has been incorporated with a capital of \$100,000. The directors of the company are Eli Edwards, Perry Deckard, Fred

Mason, Otho Seldomridge and Thomas L. Jones.

Cairy Littlejohn, chief mine inspector and secretary of the Indiana Board of Mines and Mining, is seriously ill at the Methodist Hospital in Indianapolis, with a complication of diseases.

Recent electric-power contracts have been signed by several Indiana coal operating companies with the Central Indiana Power Co., which is now putting the new 100,000-kw. steam plant at Terre Haute into operation. The Glencoe Coal Co., of Terre Haute, has contracted for electric power equivalent to 600 hp.; the Binkley Coal Co. for 300 hp. for its Essanbee mines; the Shirkie Coal Co. for 500 hp. for its Shirkieville mine and the Newport Coal Co. for 300 hp. for use at Newport.

KENTUCKY

Several coal tax bills have been introduced in the General Assembly. One provides for a tonnage tax on coal based on either 2½ or 3 per cent of the sales value of the coal produced and sold.

On the night of Jan. 29 persons using a pass-key entered the district office of the United Mine Workers at Harlan and took the union's complete set of books, including cash book, ledgers, and minute books of six locals which kept their records at the Harlan office. On Jan. 1, it was reported that a stick of dynamite with cap attached was found hanging in the building, and since that time the union officials quit sleeping at the headquarters office.

An arrangement has been closed with the Phoenix Coal Mining Co., of Louisville and Nashville, with mines at Drakesboro, whereby the **Nashville Coal Co.**, of Nashville, Tenn., a jobbing concern, will take the entire output of the Phoenix mines under contract. The Nashville Coal Co. has arranged to open an office in Louisville, in charge of C. W. Logan, who has been sales manager for the Dixie Fuel Co. The Nashville Coal Co. has the output of the Southland Coal Co., of Henderson, and the Panama Coal Co., of Robards, under contract.

It is reported from Hopkinsville that the **Dixie mine**, of the Memphis Coal Co., at Mannington, has been leased to **Holly Jackson and G. B. Watson**, of that place, who have started operations again. It also was stated that this is the only tippie mine in Christian County doing a railroad shipping business that is operating at present.

MINNESOTA

The Lignite Coal & Byproducts Corporation, of St. Paul, has filed application with the State Securities Commission of North Dakota to sell stock to the amount of \$100,000 in a \$1,000,000 corporation. The company is headed by Dr. Hans Holzwarth, a German chemist, and is incorporated under the laws of Delaware. It proposes to build a plant at Richardson, N. D. P. Hoenerback, of Richardson, is president. A similar petition has been made to the State Securities Commission of Minnesota.

MISSOURI

Surface water flooded the **Jacob Gohring coal mine**, three and one-half miles west of Fulton, on the Columbia road, doing damage that cannot be repaired and that forced the closing of the mine. Mr. Gohring said that the rock top of the mine broke at night and let the water flood in. The shaft was put down three years ago.

NEW YORK

An exhibit of the hard-coal industry under the direction of the General Committee of Anthracite Operators, at 13 East 45th Street, New York City, is being largely attended. The exhibit is similar to that opened in Philadelphia several weeks ago.

P. G. Paris, director of the Westport mill investigation and testing laboratory of the Dorr Company engineers, has resigned to return to the Bethlehem Steel Co., with which he was formerly affiliated. He will be connected with the patent and research department and will be a consultant on ordnance work. The directorship of the

Westport Mill will be taken over in the near future by **J. A. Baker**, who was formerly connected with the Dorr Company.

Fines totaling \$80,000 were imposed against the Buffalo, Rochester & Pittsburgh Railway Co. and the Rochester & Pittsburgh Coal & Iron Co. on Jan. 30, when they pleaded guilty to charges of violating the Elkins act. The case was before Judge Morris, in federal court at Buffalo. The two companies were alleged to have agreed that the railroad should not collect demurrage charges. The period in question was 1922, when the coal strike was on.

Stockholders of the Lehigh Valley R.R. will be able to subscribe to the stock of the **Lehigh Valley Coal Co.** until June 15, the right having been extended from April 15, according to a letter sent out by President E. E. Loomis, of the railroad company.

NORTH DAKOTA

The Lignite Coal & Byproducts Corporation has been formed to develop the lignite fields of North Dakota. **Hans Holzwarth**, an engineer, who is to be the president, announced during an address delivered in Minneapolis, that a distillation process developed by Thyssen & Co., in the Ruhr under the supervision of the former chief engineer of the company, is to be used in a \$350,000 plant at Richardson, N. D., to convert lignite into briquets with the heat value of anthracite; into rare and valuable gases, into pitch, tar, fuel oil, benzene, and if profitable, into a score of other products.

Production at the mine at Haynes, N. D. owned by the State of South Dakota has reached a high point during the past year, touching average monthly shipments of 150 cars. These figures are far from capacity production, but are really around 50 per cent.

OHIO

The Virginia & Kentucky Coal Co., Cincinnati, has been chartered with an authorized capital of \$25,000 to mine coal and sell and deal in coal and coke. Incorporators are M. Wellman, F. H. Dunker, Elizabeth Dunker, Margaret Shumate and J. B. Shumate.

The Preston-Morgan Coal Co., of Columbus, has been chartered with an authorized capital of \$50,000 to mine, buy, sell and deal in coal and coke. The company has a mine located near Nelsonville. In addition to handling their own product the company will also do a general jobbing business. Offices are located in the Atlas Building. Organization has taken place by the election of C. L. Preston, president and Vance Morgan, secretary and treasurer, both of whom were formerly connected with the Snake Hollow Coal Co., of Columbus. Other incorporators are E. L. Preston, F. L. Preston and Mabelle E. Preston. **The Snake Hollow Coal Co.**, located at 547 Atlas Building, has been partially reorganized since the chartering of the Preston-Morgan Coal Co. George M. Merritt having been made president and George W. Merritt, sales manager, taking the place of Charles L. Preston, who heads the Preston-Morgan Coal Co. The company maintains operating offices at Nelsonville and in addition does a general jobbing business.

The Harribel Coal Co., Bridgeport, has been incorporated with a capital of \$100,000 to buy, sell and mine coal. Incorporators are P. F. Gilhooly, D. W. Bowen, David McGary, John E. Fulton and S. M. Barr.

OKLAHOMA

The Pine Mountain Coal Co. of Heavener has increased its capital stock from \$47,000 to \$65,000. This company carries on coal-mining operations in the vicinity of Heavener and is planning to enlarge its operations there.

C. H. Hyde has filed before the Corporation Commission of Oklahoma a petition asking that the commission take up the question of coal prices in Oklahoma. Mr. Hyde represents the Farmers' Union of Oklahoma in the action taken. It is alleged that prices charged the farmers for coal at Henryetta are unreasonable and excessive, and it is asked that the commission take cognizance of the situation and under its authority in anti-trust matters that it regulate prices charged for coal in the state.

The Lamont Fuel Co. of Henryetta has been organized with a capital stock of \$25,000. The company will conduct coal-mining operations in the vicinity of Henryetta. Incorporators are J. E. Lamont, Sue Lamont and H. A. Booth, all of Henryetta.

PENNSYLVANIA

Joseph J. Walsh, State Secretary of Mines, has named a special committee to investigate the cause of the Shanktown mine disaster, in which thirty-six miners lost their lives. The committee consists of Thomas S. Lowther, of Indiana, Pa.; T. J. Lewis, of Punxsutawney, and Nicholas Evans, of Johnstown. All of the members of the investigating committee are bituminous-mine inspectors and they started their investigation Feb. 6. The committee will be joined during its investigation by J. W. Paul, of the U. S. Bureau of Mines.

The State Workmen's Compensation Board has modified its ruling relative to hospital expenses in compensation cases. The original ruling, adopted in 1919, provided that in accidents happening after Jan. 1, 1920, "where there are both medical and hospital charges, or hospital charges alone, the board will rule \$100 as a maximum charge of the latter." This \$100 maximum payment to hospitals has now been removed but the burden of proof that the expenses have been greater than this amount is placed upon the hospital. The board will consider all cases on their merits.

The Okonite Company, Passaic, N. J., has recently opened a branch office at Pittsburgh. It will be in charge of Edward A. Damrau, district manager.

The Department of Mining and Industry at Harrisburg reports that during the forty-seven weeks that the mines were operating 18,873,000 net tons of anthracite was mined in Lackawanna County. In 1922, when work was suspended for five months and eleven days, only 11,283,004 tons was produced. Last year's tonnage, however, fell short of the output of 1919, 1920 and 1921, when 19,631,494, 20,023,567 and 19,695,315 net tons was mined, respectively. The total output in Pennsylvania for the year 1923 is shown in the reports to have been 89,600,000 net tons.

Not a single fatality occurred in 1923 from gas or dust explosions in the bituminous mines of Pennsylvania, according to Joseph J. Walsh, Secretary of Mines. There were 195,000 persons employed in the bituminous mines. Secretary Walsh said that there is sufficient methane expelled daily from the bituminous mines to make 30,000 tons of firedamp. Eight hundred million tons of air was pumped into the mines to drive out the gas and, according to the Mines Department chief, the air passing through the mines last year in the ventilating systems weighed approximately eight times as much as the coal mined.

A state charter has been issued at Harrisburg to the Southern Anthracite Collieries Co. of Wilkes-Barre, with a capital stock of \$5,000. The incorporators are T. H. Rippard, Wilkes-Barre, treasurer; Walter J. Bennett, Towanda, and Harry A. Mackie, Kingston. The purpose of the corporation is to acquire coal and coal land.

The Davis Coal & Coke Co., Uniontown, has been incorporated with \$25,000 capital. The company will mine coal and manufacture coke and sell them. John A. Henry, Uniontown, is the treasurer of the company and the incorporators are W. J. Reilly and M. W. Callaghan, of Uniontown, and J. L. Miller, Wilkingsburg.

A state charter has been issued to the Blanchard Youghiogheny Coal Co., Pittsburgh, mining and preparing coal for the market. The company has a capital stock of \$5,000 and J. S. Trageser, Pittsburgh, is treasurer. The incorporators are William G. Blanchard, P. W. Rainer and W. C. Jamison, Pittsburgh.

UTAH

A. D. Pierson, former head of the sales department of the Utah Fuel Co. and widely known throughout the mountain states and Pacific Northwest as a coal man, has left for San Francisco, where he will act as district sales-manager of the Utah Coal Sales Agency, a branch of the United States Fuel Co. of Salt Lake City. Of late Mr. Pierson has served the United States Fuel Co. as railroad fuel agent. He will be accompanied to the Coast by Frank W. Morrison, chief clerk.

Coal production in Utah in 1923 totaled 4,627,570 tons, compared with 4,892,657 in 1922. The State Mining Department said another 40,000 could be added to the 1923 output on account of mines worked by farmers.

The Star Coal Co., of Ogden, has filed articles of incorporation showing capital stock amounting to \$1,100,000, divided into 100,000 shares of common stock of par value of \$1 and 100,000 shares of preferred stock of \$10 par value. Charles H. Smith is president and James L. Donnelly secretary-treasurer. The property of the company is in Lincoln County, Wyoming.

The Utah Briquetting Co. has applied to the State Securities Commission for permission to sell 5,000 shares of common stock at \$10 per share. The company proposes to manufacture briquets for fuel from slack coal and lignites.

WEST VIRGINIA

Interests identified with the Youghiogheny & Ohio Coal Co. have organized the Simpson Creek Collieries Co. and have taken over the property and holdings of the Simpson Creek Coal Co. in West Virginia. It was announced at the annual meeting of stockholders at Baltimore on Feb. 6. This property consists of approximately 2,700 acres of thick-vein Pittsburgh coal in Taylor and Barbour counties, in the Fairmont region. The consideration involved in the transaction was not made public. It was announced that the Simpson Creek Coal Co. would retain its corporate existence, with its present staff of officers.

The Kingston Pocahontas Coal Co., operating at Hemphill, announced a reduction in wages effective Feb. 1, notices to that effect having been posted at the mines. It is stated that there has been a reduction in all classes of labor amounting to 10 per cent at the Exeter operation and affecting 125 men. At the Warwick operation of the same company the cut amounts to about 20 per cent and affects about 350 men. For some time these plants have been running only about 20 days a month. The company hopes, by adjusting its wage scale, to be able to run the mines day in and day out.

According to compilation made by the West Virginia Department of Mines 70,188,203 gross tons of coal was produced in the state during the fiscal year ending June 30, 1922, through the use of 5,786,752 lb. of permissible explosives. A table prepared by the department shows that 396,561 kegs of powder and that 380,268 lb. of dynamite were used, with 888 operations reporting. The cost per keg of powder to the miner, taking the state as a whole, was \$2.39 and the cost per pound of dynamite 22c. More powder was used in Logan County than in any other county in the state in the fiscal year, the quantity being 88,008 kegs of powder and 495,263 lb. of dynamite. Mines in McDowell County used more dynamite than the mines in any other county in the state, the quantity being 132,792 lb. In the same county 86,008 kegs of powder was used. McDowell County mines led those of any other county in the quantity of permissible explosives used, 1,334,254 lb.

Two large blocks of coal have been shipped by the Consolidation Coal Co. to Italy for exhibition purposes. One block weighing six tons was removed from Mine No. 22 of the company, at Monongah, and sent to Baltimore to be shipped to Genoa, Italy, as a part of the company's industrial display. This block was 4½ x 4½ x 8 ft. and is described as one of the largest ever removed from northern West Virginia. It is low sulphur coal. Another block weighing five and a half tons, 9 ft. high and 4 ft. square was shipped on Feb. 3 from the Hoffman No. 3 mine, near Eckhart, in the Georges Creek field, to Baltimore and is now on its way to Milan, Italy, where it will be displayed at an industrial exposition. The coal is from the Georges Creek big vein. It required seven days work by four miners to cut and remove the large block.

As a result of wage reductions in some of the fields of southern West Virginia some mines are operating on the 1917 scale. No general or concerted action, however, has been taken among the operators of non-union mines in adjusting wages to meet prevailing market conditions. Such action has been taken only where it was necessary in order to continue operations or to resume operations. Some of the mines in the New River field are operating under such readjustment also some in the Winding Gulf and the Kanawha fields. The basic wage for mine labor in the New River field amounts to about \$7.50 a day. The reduction approximates about \$2 a day in some instances. As a rule wherever the new scale has been posted the miners have accepted the decrease and in some instances have asked for it, in order to permit a continuance of operations.

WISCONSIN

The Carnegie Dock & Fuel Co. has won its tax case in the U. S. District Court at Superior. The company was taxed about \$8,000 for railroad coal held on its docks. The District Court held that the coal was railroad property, despite its location, and was non-taxable. This case was in the nature of a test, as all other docks in Superior have similar tax problems.

January shipments from the Head-of-the-Lakes docks will run close to 24,000 cars, as compared with 17,000 cars in December. Much of this movement is on back orders. It is estimated that 4,600,000 free tons are still on the docks.

WASHINGTON, D. C.

The committee appointed by the National Coal Association to study the English coal exchanges consists of the following members: F. W. Wilshire (Chairman), vice-president, Consolidation Coal Co., New York City; T. F. Farrell, second vice-president, Pocahontas Fuel Co., New York City; H. N. Taylor, president, United States Distributing Corporation, New York City.

W. M. Fridell, district manager, Washington Coal Co., announces that the company has opened a new office in the Kresge Building, 11th & G Sts. This concern is a large wholesale coal dealer.

CANADA

Canadian Collieries (Dunsmuir), Ltd., is unwatering No. 8 mine, at Courtenay, Vancouver Island, and will commence mining operations as soon as the mine is free from water. Locally, the mine is known as the mystery mine, because some ten years ago it was equipped with the most modern machinery available at that time but no coal has been taken from the property since, probably because of low market. Included on the property were 60 houses for employees, 20 of which, however, were destroyed by a brush fire last spring. The coal in some of the company's other mines is now being mined at long distances from the surface and No. 8 mine can be operated more cheaply.

The Vancouver Island Branch of the Canadian Institute of Mining & Metallurgy met in Cumberland, B. C., on Jan. 12. Charles Graham, district superintendent of the Canadian Collieries (D), Ltd., presided. George O'Brien, safety engineer with the Canadian Collieries, gave a talk on "Ancient and Modern Methods of Gas Detection and Mine Illumination," in which he referred especially to the efficiency of the Burrell Gas Detector. He predicted that it would not be long before the flame gas detector was entirely eliminated in coal-mine work.

A demonstration of the coking of several carloads of Nova Scotia and New Brunswick soft coal took place at the official opening of the new coking plant of the Hamilton Byproducts Coke Ovens, Ltd., at Hamilton, by Charles Stewart, Minister of the Interior and of Mines. Dr. Charles Camsell, chairman of the Dominion Fuel Board, and a number of other government and company officials were in attendance. The result was regarded as highly satisfactory confirming the tests made by the Dominion Fuel Board at the laboratory at Ottawa. Mr. Stewart deferred making any positive statement until an analysis had been made by the government chemists, who will continue their investigations at the plant for a week or so. He, however, expressed himself as most hopeful that their findings would be favorable and prove that a solution of the fuel problem had been reached by the coking of soft coal for domestic use. The Hamilton plant represents an investment of \$4,000,000 and was designed and built by the Smet-Solvay Co.

During the month of December, 1923, there were produced in British Columbia 210,151 tons of coal, an increase as compared with the output for November of 9,636 tons. Of this the Vancouver Island field is credited with 135,361 tons, or 64.46 per cent of the provincial total, an increase as against the previous month's figures of 2,966 tons. The Nicola-Princeton Mines produced 20,067 tons in December, which is 775 tons less than in November, while the output for the Crow's Nest Pass field during December was 54,723 tons, an increase of 7,445 tons, or 26.04 per cent of British Columbia's production for December.

New Equipment

An Underfeed Stoker

The Combustion Engineering Corporation, of New York, has recently developed a new stoker called the Frederick Multiple Retort. It operates upon the true underfeed principle and is built in central and superstation types.

The retorts have a relatively large

Fig. 1—Stoker Using Underfeed Principle

The fuel is first fed to the coking region and then on into the center of the fuel bed, where it burns over tuyeres of novel design.

main feeding ram 9½ in. in diameter, feeding approximately 20 lb. of fuel per stroke. The strength of the connecting rod, steel crankshaft and bearing brackets is considerably increased to provide a large margin of safety. The shearing pin is designed to receive a positive shearing stress at all times.

Two sprockets of different ratio are employed on the speed shaft, allowing each gear box to be operated at a different capacity. In the large types this makes the maintenance of an even fuel bed more positive.

The secondary ram, as shown in Fig. 2, is said to be one of the most notable of recent advances in the development of stokers; the fuel-feeding and fuel-agitating parts are composed of tuyeres forming an active fuel-burning surface. The tuyere design—also a

Fig. 2—Secondary Ram

The design of this ram is such that it pushes the fuel and supplies air to the re-arranged coal.

new feature—has curved vanes which insure proper guiding of the air into the fuel bed and an even air distribution without any shock.

The underfeed section is inclined 20 deg. from the horizontal and its large area within a certain furnace dimension provides for the prevalent tendency to increase combustion rates and makes it possible to do so without excessively high combustion rates per square foot of grate surface. This increase in underfeed grate area is accomplished

by dispensing with the usual long extension grate. In this way it is possible for the secondary ram to gradually force the green or uncoked coal into the entire fuel bed.

A row of non-clinking furnace blocks is installed above the retort caps as part of the stoker. These blocks form an air space to which air is supplied from the stoker windbox. The air passes through the hollow retort caps, cooling them, and then passes across the fuel bed through the perforation of each block.

Each stoker also is equipped with air-cooled dumping grates, which prevent the forming of clinkers.

E M B Resistance Again Obtainable

During the war many mining men found that E M B Resistance was not obtainable and no doubt they will be pleased to know that this resistance is now being handled by the C. H. McCul-

Fig. 1—E M B Resistance Elements

lough Engineering Co., 2327 Oliver Bldg., Pittsburgh, Pa.

This resistance is produced from long drawn out ribbons of unbreakable and rustless material. Each bank of resistance consists of a long jointless piece of this material set in the usual form of resistance box frame. The material making up the resistance is drawn absolutely uniform in cross-section and therefore, according to the manufacturer, there is no risk of local fusing. To take out taps or connections, terminals of high-grade gun metal are bolted to loops in the resistance and therefore the spacing of controller attachment points is very readily made.

Section Insulator Switch with Grounding Attachment

Fig. 2—Resistance Banks for Mine Locomotives

For mining service, these resistances have been applied to various types of machines, being most successful on mine locomotives, coal-cutting machines, coal loaders and hoists where there always is considerable vibration.

Locking-Type Section Insulator Switch

A locking-type section insulator switch, primarily designed to comply with the Pennsylvania compensation rating schedule, but a desirable design for any mine, is the latest addition to Ohio Brass Co. section switches.

The switch has a knife-switch blade and contact clip on the top which are engaged when the switch proper is opened. A permanent grounding cable can be installed in a lug on the switch, so that when the trolley circuit is opened, the dead side becomes grounded. The switch clip on the top has holes for insertion of a padlock, which locks the switch open.

These two features make compliance with the Pennsylvania schedule quite simple, as they incorporate all of the requirements for a section insulator into one piece of apparatus and preclude the need of special attachments or special methods of overhead construction.

The lock switch also has the new method of suspension provided on the later O-B switches, which consists of support brackets set at a comparatively low point on the ends of the insulating member. This shaping permits the use of insulated hangers without need for cutting into the roof for clearance or for raising the switch. The switch is supported in a higher position so that the general height of the trolley is not affected where a section switch is installed.

Setscrew lugs at each end of the switch provide a means for running a feeder line through the switch, the feeder line thus being opened when the trolley circuit is opened.

Those Massachusetts Coal Tests

IN THIS issue O. P. Hood records his findings in Massachusetts as to the quantity of ash in anthracite. It is a little disturbing to read that it is necessary to take 1,000 lb. samples. Portentously we are told that a correct method of sampling coal has been devised and that to this end 1,000-lb. samples must be taken. How bold it is to question such a redoubtable standard as this seems to be! But the dictum is so positive that it sounds convincing. However, perhaps it is not more necessary to take a thousand pounds than to carry *pi* to ten places when calculating horsepower from the area of a piston or to use ten places of decimals in calculating co-ordinates for a mine survey.

After all there is in the lives of all of us something more important than meticulous accuracy. Some people will haggle over a cent and lose a dollar, will fuss over three or four inches in the width of a farm and then to save the expense of another survey will take the next area on faith; measure to hundredths of a foot yet fail to close a survey by four or five minutes.

The Bureau of Mines seems possibly in danger of this. It would do well to have a standard less meticulous and apply it more often. It seems too much like cutting down a forest to find how many board feet can be obtained from it.

The public is not so much interested as to whether its coal has one or two per cent more or less ash than a certain standard, but it is interested in knowing that it does not have twenty or thirty per cent more and in stopping all those who are putting such unburnable rubbish in the home, the factory and the market.

The law is not so much to exhibit authority with the responsible producer but to make matting unbearably hard for the irresponsible man just as soon as he tries to get into the market.

Trying to make too close and too expensive a survey will result ultimately in no survey being made. As engineers and not theorists the Bureau of Mines should seek to serve the public in the most practical way possible, and that is done not by attempting too much refinement in analysis but by a broader survey of conditions with less perfect analyses.

We are not convinced by the argument that as the value of a ton of coal is greater than that of a ton of ore so large a sample should be taken. The ore is improved by crushing. That indeed is the first step in beneficiation. Coal is spoiled by the same process. Crushing coal is not a beneficiating step but a degrading one. The difference is not one of words but of facts. If all the coal were bettered by crushing, the operator willingly would let the government crush it all and take a 50-ton sample, but seeing that this is not true even a 1,000-lb. sample looks large.

To revert to another phase of Mr. Hood's papers, in large letters should be written the fact that the Bureau found dealers mixing dirty and clean coals together,

hoping to make the dirty coal salable. The extent to which this is done, especially in times of shortage, should make anthracite operators take action. The public is shown shipping slips from responsible operators and is delivered coal in which that company's product may form only a small percentage.

Against the Day of Rain

WHEN it is fine weather, says the old proverbial saying, it is needless to repair the roof, and when it rains the roof cannot be repaired. This holds true of correcting the evil of dirty coal. Just now there is not much trouble with coal quality and the public clamor is stayed, so why fuss about the matter? Let it lie, is the general dictum. Nevertheless during this fine weather is the best time to repair the roof of industry and not during the day or days of rain.

Today the industry can take matters in its own hands. It can convince the public that it means business. When a strike threatens or comes it will be too late. The public may—probably will—enact some statute the industry will not like. Before it does so the coal producer will be besmirched. He may get more than government inspection. He may get government regulation; even government ownership. A little shingling of the roof now may save more drastic action later.

No one can hide one's face to the fact that during all shortages of anthracite and bituminous coal all kinds of impure product found its way into the market. In the anthracite region men, either from that region or from others, loaded culm banks unwashed. Men who knew nothing more about coal than that anything remotely resembling it would sell went into the business of producing it or at least of gathering it up.

So bad was it along one line of railroad that the principal producer caused the coal in cars loaded by others to be sampled so that if an investigation came that company could assure Congress of the real source of the coal and exonerate itself. The investigation never came, but the indignation did, and the principal coal company on that road, the one connected with the railroad, unquestionably got the blame and yet had no chance to make a disclaimer.

In fact all the big companies in the anthracite region came in for a share of it, for when dirty coal comes into the market the outstanding companies must bear the brunt. It must be they who are at fault, says the man on the street, for see how rich they have become. The average man cannot understand that a large company more often grows on honesty than on crooked dealing.

In the bituminous field it was little different. The waste from washeries mysteriously disappeared being loaded into cars. Some of this inferior coal may have been sold for just what it was, and the buyer in that case may not have been deceived, but some doubtless were. Here again the whole industry suffered. How-

ever, it is not so detrimental when industrial purchasers are defrauded. As they buy in carload lots they can make their claims for damage direct, and they can go elsewhere in future. Buying in large quantities, it is worth their while to bring suit, and the producer, knowing that fact, is obliged to be reasonably careful.

But the domestic buyer is often obliged to deal with one merchant, no matter how ill he serves him, and even if he has a choice the dealer may be able to convince him that the coal was bought as a good product and that he is more sinned against than sinning. Furthermore, dealers can easily bring pressure on buyers. A purchaser often fears to complain. He might be refused coal when next he wanted it; he might even quietly be blacklisted. After all it is difficult to remove coal from a cellar, and once there it stays there and the buyer pays. Certainly it does not pay to go to court for a winter's coal or less.

"Let the buyer beware" may be good English and American law. If, however, a man gives us a bad bill or a bad dollar, do we believe that we are to blame and that we should have been on our guard? It is well to remember that much good law is bad morals and to quote bad law in defense of the questionable conduct even of our unfair competitors is little but a folly.

John, Rex, Still Rules

THE loose talk about an impending split in the United Mine Workers because of dissatisfaction with the rule of John L. Lewis is not convincing. Lewis is in no worse position before his own people now than most other presidents of the United Mine Workers have been at various times in their invariably tempestuous careers. Nobody can be head of the miners' union without serving as target for all the decayed fruit within the reach of the union malcontents. There always was and always will be rebels in the union and some day they will run Lewis out just as rebels so frequently have done to other presidents. But there are no signs that Lewis is now on his way. He has as much power as he ever had to make his people respect contracts.

The fact that reds made a loud noise in the miners' convention at Indianapolis last month means nothing much. The total number of real radicals did not pass 250, but 250 reds, seeing they could worry 1,700 in a convention, naturally kept up their disturbance. Quite a number of others joined in for fun, judging by their remarks. A two-weeks' miners' convention simply must have a bit of diversion to break up the droning of committee chairmen.

Even the fact that the administration had a close shave in the one roll call of the convention—a vote on the question of whether Lewis should be stripped of the power to appoint organizers—does not indicate that the union is on the point of splitting. It does mean, however, that dissatisfaction with Lewis on that particular matter is widespread and that the feeling has rolled up so much intensity that something will have to be done about it. Lewis is crafty enough to do something.

He will manage, before the next convention, to use his appointive power so judiciously that the issue will not be so formidable again. The chances are that organizers will give a better appearance, in the future, of earning their monthly \$300 pay checks. They will serve the whole organization instead of its president.

Anyway, Lewis will devote more of his undoubted genius to making those organizers popular with the rank and file. He nearly lost his right to choose them; he cannot afford such a loss. If he could not appoint them, a few disloyal organizers, elected by districts, might well produce a real schism in the union. There is no dangerous schism now. John L. Lewis, virile as a power plant, still rules.

"Consolidate!" They Cry

FEVERISH movement toward consolidations of mines in various bituminous-coal fields is gaining headway daily. Operators both strong and weak turn their thoughts upon it—the former in the hope that it will improve conditions of operating and marketing; the latter in pure desperation. In some regions the proposal is overshadowing almost every other subject except wages.

Of course, consolidations are logical at a time like this. An industry 30 per cent overdeveloped and for years harassed by cut-throatism within itself certainly needs stronger business units and fewer fly-by-nights. But consolidation is no panacea for all the ills of coal. It should not be looked upon as a rejuvenating monkey gland to be hastily and recklessly ingrafted on any and all devitalized coal companies. If such companies cannot justify their existence separately, consolidations should not and probably cannot save them.

The natural desire to bunch together for mutual protection has led operators to consider some grotesque schemes for business groupings. Most such schemes are hopeless. For instance, in a field where many small producers have worked their own undoing time and again by mutual distrust and stealthy price cutting, what hope would there be in a "consolidation" which consisted only in the various companies selling through a common agency? There would be no accurate control over the entire output of the mines involved. There would be no reduction of mine costs through central management. There would be much opportunity for discrimination as between members. The cohesion of the group would be weak. It would fly apart on small provocation and upset the market and conditions generally. It would be no consolidation at all. Any half-hearted plan for weakly linking up mines or partially pooling properties is a futile dream.

The only permanent and substantial benefits from consolidation will be enjoyed by those properties which have an unquestioned right to continue serving the public and which form natural and logical groups under single ownership and control. However, we may expect to see and hear a good deal during the next few months about other sorts of coal properties being buffeted about through one scheme after another until the elimination process has done its worst.

But this consolidation wave will not engulf every independent company. It will help natural processes wash out bone and dirt, leaving the industry somewhat purged. While this is going on, good operating men everywhere, both in consolidation and out, will continue to be surprised at their own ingenuity in whittling down the costs of coal, the mechanizing of mines will spread apace, and about 5,000 good properties will continue prosperously to supply the nation's tremendous demand for half a billion or more tons of coal every year.

Can the Valley Coal Fields of Virginia Compete With Those of the Anthracite Region?

Coal Is Semi-anthracite, Slightly Lower in Rank Than the Lykens Valley Product, but That Is an Advantage
—Ash Content High, Being from 14 to 28 per Cent

MORE promising than the rest of the coal areas of Montgomery, Pulaski and Wythe counties of Virginia are those which have been named the Valley coal fields. They recently were examined by the U. S. Geological Survey and the Geological Survey of Virginia to ascertain their extent and value.

The most important questions concerning these coal areas are: What is the quality of the coal? Is it an anthracite, and if so can it successfully compete with that of Pennsylvania? If it is not an anthracite, has it distinctive properties of its own that will please the consumer and lead him to continue its use?

The accompanying table contains all the recent government analyses of this coal. These should be carefully studied by anyone who contemplates investing in this field or handling the coal, for they afford the means of determining the rank, grade and market possibilities of the fuel.

COAL IS NOWHERE A TRUE ANTHRACITE

The Geological Survey reports unqualifiedly that this coal is not an anthracite. An anthracite, according to the accepted meaning of the term, is a coal so low in volatile constituents that it burns with a bluish flame only and not the short yellowish flame that is characteristic of the Valley coals. A comparison of the analyses of samples of anthracite shows that in coals which burn with a blue flame the volatile matter is one-tenth or even less than one-tenth of the fixed carbon.

NOTE—The facts in this article are supplied by U. S. Geological Survey, which expects later to publish a printed report.

As the supply of Pennsylvania anthracite is decreasing and its price is steadily mounting there is an eager and growing demand for a satisfactory and cheap substitute. Many of those proposed are more or less satisfactory, but one of the most promising, especially for use in the Middle Atlantic States, the Mississippi Valley, and the Great Lakes region, is a semi-anthracite that is mined in fields in southwestern Virginia, in or near the Great Valley, in Montgomery, Pulaski and Wythe counties.

This relation generally is expressed as the quotient of the percentage of fixed carbon divided by the percentage of the volatile matter. This is called the fuel ratio. The fuel ratios of the Valley coals are given in the last column of the table of analyses. This table shows that the coal of highest rank from the Valley fields has a fuel ratio of 8.5. The fuel ratio of anthracite of the lowest grade is 10, so that all the coals here considered are below the rank of a true anthracite.

This coal evidently is not an anthracite and should not be placed upon the market under that name. The next question is: Has it distinctive properties which will enable it to compete with Pennsylvania anthracite or which will cause it to be so liked by the consumer that he will prefer it to any other coal on the market?

The answer to this question must depend largely upon how well the Valley coal is prepared before marketing, but if it can be so treated that the ash will not exceed 8 per cent this coal may possibly obtain a market of its own that can be held against all comers.

The coal with which the Valley product is most often compared is the Lykens Valley coal, which occurs at the west end of the Southern Anthracite field of Pennsylvania. This coal commands a substantial premium above the highest rank or "dry" anthracite, because it contains more volatile matter and therefore burns with a short yellow flame that makes it attractive as a grate fuel. Its higher percentage of volatile matter also makes it ignite more readily than ordinary anthracite, and this is another point in its favor.

The Valley coals are slightly lower in rank than the

Lykens Valley coal, but they are not low enough to be called smoky coals, and consequently there seems to be no reason why these Virginia coals should not find as ready a market as the Lykens Valley coal, provided the ash is reduced to the percentage above noted.

If the Valley coal is not an anthracite, what should it be called? It has just been shown that this coal should not be classed as anthracite because its percentage of volatile matter is too high, but the analyses show that it is only slightly below that rank. In other words, it must necessarily fall into the next lower rank. The next rank below anthracite is semi-anthracite, and this rank includes coals whose fuel ratios range from 5 to 9.9.

The table of analyses shows that practically all the coals of Montgomery, Pulaski and southern Wythe counties fall within this rank, though they differ considerably among themselves. The coals of the Price Mountain and the Pulaski fields head the list and are followed closely in descending order by the coal mined at Empire, at Gunton Park, and lastly by other coals of the Little Walker Mountain and Brushy Mountain fields.

The Valley coal now being mined should therefore be marketed as a semi-anthracite, but if properly cleaned it will perhaps be an even more attractive fuel for some purposes than the "dry" anthracite of the Pennsylvania fields.

The coals of the Reed Creek and Bland fields seem to fall below the rank of semi-anthracite, but as all the

samples available for analysis consisted of more or less weathered coal they may not correctly represent the real unweathered coal. If unweathered material were available analyses might show that the coal belongs to the same rank as the coal of the fields to the south.

SOME BONY COAL QUITE HIGH IN VOLATILES

At most places in these fields the coal beds that are mined show a great variety of coal, some of it very soft and flaky, some hard and bony, and some that resembles black sand. No two operators or even miners agree as to the real nature of these peculiar kinds of coal or as to whether they should be classed as coal or as bone. In order to settle some of these questions samples of two of these varieties were analyzed.

Sample 94,182 is so-called "sand coal" from the Merrimac mine, in the Price Mountain field. This coal is common in the Merrimac bed wherever it has been mined and prospected. The analysis is rather surprising, as the "sand coal" contains more volatile matter than the coal in the rest of the bed. Thus, a mine sample which was obtained in a cut across the coal bed and which included all except the distinctly bony layers showed on analysis 9 per cent of volatile matter and 17.1 per cent of ash, whereas the "sand coal" from the same locality showed 22.3 per cent of volatile matter and 25.2 per cent of ash.

The explanation of the high percentage of volatile matter is found in the composition of the coal. Under

The form labeled "pure coal" is only moisture and ash-free coal. No. 95,621 is a grab sample of dull splint coal. No. 94,182 is a grab sample of so-called "sand coal." No. 95,620 is picked coal from a weathered stockpile. Nos. 20,721,

93,670, 95,405 and 95,406 are from old caved prospects, and the coal is doubtless affected by weathering.

New River from the Parrott Coal Mine, New River Field, Virginia

The Parrott mine is operated by the Pulaski Anthracite Coal Co., on the Norfolk & Western Ry. It is located in the Merrimac bed, the same which is operated by the celebrated mine of that name. The area across the New River is Montgomery County.

Though the river is the same, this field, despite its name, is far removed from the better known New River coal region of West Virginia, which is on the lower reaches of this same river. The measures here are far older than those in the West Virginia

field, the volatile content of the coal is much lower, and the coal has considerably steeper pitches. The dip varies from 35 to 50 deg., making the area of extractable coal only about half a mile wide, provided the dip continues thus far without diminution.

the microscope the granules, which resemble grains of black sand, were seen to be seeds and spores of plants—the most waxy or fatty material that is found in coal. This waxy material gives to the “sand coal” its high content of volatile matter. Its high content of ash relegates it to the class of bone, and it should be thrown out by the pickers unless in some way its good materials may be utilized and its bad ones eliminated.

The Merrimac bed in many places contains a layer of dull coal that resembles gray splint. A sample of this material was obtained from a car of coal from the mine of the A. Dunphy Coal Co., which is just south of the old College mine on Toms Creek, northwest of Blacksburg.

Sample 95,621 consists of dull splint-like coal, and the analysis shows practically no difference between this sample and one representing the entire coal bed in the College mine, except that the coal from the Dunphy mine contains more ash. Here again the material should be classed as bone and discarded unless the percentage of ash can be materially reduced.

THERMAL VALUE OF PURE COAL HIGH

The table of analyses shows the poor points of the Valley coal as well as the good points. The good points include the extremely low content of sulphur and the high heating value of the real coal substance expressed in British thermal units under the heading “Analysis of pure coal” in the table. The striking uniformity of the quantities in this column shows that even the possibly weathered samples would have a heating value comparable with the coals of higher rank were it not for their large content of ash. A comparison of the figures in the two columns headed “British thermal units” affords a ready means of finding the loss in heating value due to the ash and moisture in the coal as mined.

The worst feature of this coal is its high percentage of ash, which in the samples cut in operating mines runs from a minimum of 14 per cent to a maximum of 28 per cent. So high a percentage of ash really prohibits its successful marketing, and operators must make more vigorous efforts than they have made heretofore to reduce the ash, or else they cannot hope to establish a permanent trade in the face of keen competition. It is hardly possible to say what quantity of ash is permissible, but a strong effort should be made by

careful picking and washing to bring the quantity within 8 per cent. If such a reduction could be made it would increase the heating value to about 13,700 British thermal units and would provide a domestic fuel that need not fear competition in any market.

Boiler and Power-House Operation

“THE Supervision and Maintenance of Steam-Raising Plants,” by Charles A. Suckan, is the title of a new book just published by Ernest Benn, Ltd., 8 Bouverie St., E. C. 4, London, England.

In keeping with necessity and the development going on in large power plants toward the more economic and efficient use of fuel and advanced methods in steam raising, the author of this book has brought out many technical and practical phases of the work.

The book begins with a section entitled “Working the Power Unit.” Beginning with the organization of the power plant and describing various types of boilers, the author leads on to the subject of fuel combustion, which deals with different types of furnaces. In passing on through different methods of firing, many important details in connection with the power plant are ably discussed. Points on laying out the power plant, setting up the various structures, and their operation and maintenance are thoroughly practical.

In general the book covers the latest practices in boiler and power-house operation and points the way to improvements and developments for the future.

Splices and Tapes

AN INTERESTING pamphlet on the subject “Splices and Tapes” just issued by the Okonite Co., Passaic, N. J., deals with the importance of a perfect splice, the important properties of tape and how to recognize these properties and make a perfect splice. The promiscuous purchase of rubber and fabric tape is altogether too common a practice. This is in part due to the fact that there is no definite understanding as to what qualities a tape should possess.

The best wiring job is sometimes spoiled because of the use of a poor grade of tape at the joints or a misapplication of tape. From the troubles that frequently result it is apparent that the difference in cost between a perfect and a bad joint is hardly noticeable.

How Much Ash Is Found in Commercial Anthracite?

Test of Coal in Massachusetts Yards Discloses Variation from Lowest Ash of 10.2 per Cent to Highest of 46.1

By O. P. Hood

Chief Mechanical Engineer, U. S. Bureau of Mines, Washington, D. C.

DURING the past summer the U. S. Bureau of Mines took 127 samples of anthracite, each of 1,000 lb., representing nearly 30,000 tons of such coal in dealers' yards in seventeen cities in the State of Massachusetts. There were three objects in view: To discover the average and the variation in the quantity of ash in anthracite in some easily described area; to demonstrate standard sampling methods and to learn something about the feasibility of itinerant coal sampling. Massachusetts was selected because its principal cities could be visited in a single season. A demonstration of the standard sampling of coal seemed necessary in Massachusetts because a coal-quality law had been passed in the state which had to be administered by persons unfamiliar with the sampling of coal.

The technique of coal sampling has received the same careful study that has been given to the sampling of gold and silver ore, and as a matter of fact the value of coal per ton is greater than the value of many such ores as are bought and sold entirely on the value disclosed by proper sampling and analysis. The proper method of sampling has been approved as an American standard and should be followed. A standard sample must contain at least 1,000 lb. and be selected so as to be thoroughly representative of the lot under consideration.

This must be repeatedly crushed, mixed and quartered in a prescribed manner, until the last quarter is all finely crushed and weighs about 5 lb. Only in this way can the chance inclusion or exclusion of a piece of bone coal or slate produce a negligible effect, and the results of resampling be expected to check fairly well with the first sampling. The labor of handling and crushing so much coal, being considerable, is likely to be evaded, but in no other way can a just result be obtained.

Widely varying results obtained by different samplers tend to discredit such work, and poor sampling should have no standing in the courts. The Bureau samples were all taken in the prescribed manner, so that they are representative of the coal sampled. The Bureau used a small truck equipped with a coal crusher, arranged to be driven by the truck engine. They were taken between July 10 and Nov. 4, 1923. The cities visited and the number of samples taken in each are given in the accompanying table.

PLACES WHERE SAMPLES WERE TAKEN AND THE NUMBER OF SAMPLES TAKEN

City	Samples Taken	City	Samples Taken
Boston, Mass.	41	Brockton, Mass., (One Petroleum Coke)	11

The weighted average ash content was: For furnace size, 13.2 per cent; egg, 13.7; stove, 13.7; chestnut, 16.2; pea, 15.6; range, 19; buckwheat No. 1, 18.9 per cent. In the 8 samples of furnace coal the lowest ash was 10.5 per cent and the highest 14.6 per cent; of twenty-nine samples of egg the range was from 10.2 to 17.5 per cent; of 20 samples of stove coal, 11.3 to 15.9 per cent; of 23 samples of chestnut, 10.3 to 46.1 per cent; of 20 samples of pea, 12 to 27.3 per cent; of 4 samples of range, 13.1 to 28 per cent; of 8 samples of No. 1 buckwheat, from 13.6 to 29.5 per cent.

In the chestnut coal the highest six samples ran 46.1, 40.7, 28.3, 25.6, 18 and 16.5 per cent ash. The six cleanest samples ran 10.3, 12.2, 12.9, 13, 13.2 and 13.4 per cent ash.

Some but not all of the high-ash coal had been condemned by the state authorities. Some high-ash coal was being mixed in dealers' yards with lower ash coal.

The coal producer judges the quality of the coal by taking a small sample and by hand separating it into three piles, one of coal, one of bone and one of slate. A piece which he guesses has less than 40 per cent ash would be called coal, a piece having from 40 per cent to 65 per cent ash would be called bone, and anything having a larger amount of unburnable material would be called slate. Material can be found having almost any proportion from a very low per cent of ash to a very low per cent of carbonaceous material. The operators' standards of preparation allow in each size certain percentages of bone and slate, and also a quantity of finer sizes, but it is impossible to translate this into the quantity of ash allowable. The figures obtained by this survey give an idea of the actual quantity of ash in anthracite sent to one district in the summer of 1923, when the opinion of dealers was that the quality of the coal in general was good.

To Clean Carbide Lamp Without Injury*

By CHARLES LABBE

The usual method of cleaning spent carbide from a miner's acetylene lamp is to tap the bottom part of the lamp against the shoe and to shake out the carbide into a waste can, tapping the lamp against the rim of the can until most of its contents are dislodged. A better way is to provide a steel wire brush made from a piece of $\frac{1}{4}$ or $\frac{5}{16}$ -in. wire rope a foot or less in length. One end is served with iron wire about an inch above the end, which is then frayed out. The other end is wire wrapped about one-half inch from the end. The center portion is wrapped with tape. The short stiff end is used to loosen the carbide and the longer end for brushing it out of the cup of the lamp.

One of the weaknesses of the carbide lamp is not found in its own defect but in the way it is used. It is hammered most woefully by its user. This swab will save the container from many a hard rap on its rim, edges and bottom.

Wire Brush for Cleaning Carbide Lamps

A handy tool to keep at the receptacle where spent carbide is dumped.

"Befo' de Wah" Mine Yields Curious Relics

Engineers Prowling in Long Abandoned 1844 Bell Property of West Kentucky Find Bull Wheel, Pit Cars and Track All Made Without a Nail or Scrap of Metal—Ancient Ventilation System Works Perfectly

BY E. W. DAVIDSON
Associate Editor, *Coal Age*
Chicago, Ill.

IT IS a bit difficult nowadays to go down into a coal mine of 1844. Yet three engineers did just that. They were examining the old Bell property, near Sturgis, Ky., famous three-quarters of a century ago, in the course of studies they made preliminary to the recent rehabilitation of the mines under the present name of the Bell Coal & Navigation Co. Two hundred and ten feet of little old shaft separated the three from coal-mining days of "befo' de wah." They negotiated the distance, turned time back so to speak, and entered a strange mine containing ingenious crudities of long ago which, crude as they are, command respect from good mining men of today.

UNCOVER MOUTH OF LONG ABANDONED SHAFT

The three men were W. F. Davis, of Belleville, Ill., general superintendent of the new Bell Coal & Navigation Co.; J. A. Richmond, of St. Louis, Mo., chief mechanical engineer, and William Herbert, an engineer of Bessemer, Ala. In their examination of the noted old coal property, four miles southwest of Sturgis, in western Kentucky, they uncovered the mouth of the long-abandoned shaft—an opening known down through local history as Miners' Shaft—and decided to enter it.

NOTE—Headpiece shows equipment for clearing the way for an inspection of the mine. With a thresher engine to raise steam, with a little winch to operate the "hoist," and with a pump lowered on an improvised cage, Miners' Shaft was more or less dewatered and opened up.

A 15-ft. headframe was built over the 4 ft. 6 in. x 12-ft. three-compartment hole, a small winch was mounted nearby to operate by steam supplied by a traction engine, and the adventurers on an improvised cage, made a few experimental trips downward.

A good deal of débris had to be cleared out of the bottom, and the hole had to be dewatered by a pump lowered on the cage before the men finally flickered their candles around the bottom—the first lights that had penetrated there in the memory of any but one or two of the oldest settlers in that part of the country. They stepped into a dank dead atmosphere.

Their first sight was of a well-preserved bottom of about 4 ft. headroom, with clean-cut ribs extending up the main heading. Evidences of geometrical exactness marked everything they saw. The ribs of that main entry running back from the shaft were as true and clean as a carefully concreted entry of today. The marks of skilled hand work were on the mine ribs.

OLD FURNACE WORKS "FINE"

Proceeding a short distance up the main entry, the men found a door, long decayed, leading through a breakthrough to the right into a parallel entry. Following this back toward the shaft, they arrived at the old furnace, close to the shaft bottom, which once had ventilated the mine. The next step was to board the upcast air compartment of the shaft and erect a low

Taking a Coal Sample out of the Mine

Two of the engineers with a helper are seen here in one of the entries. W. F. Davis, the third engineer, made the picture. Marks of a hand drill are plainly to be seen scarring the rib.

canvas and wood stack on top. Then a fire was kindled in the old furnace with some misgiving as to whether the inner workings of the mine were sufficiently open to permit the furnace to ventilate the place.

"But it certainly worked fine," comments Mr. Richmond. "In less than a minute the air stream was going strong, and before long we felt satisfied we could go back into the workings and see what was there."

With no map and with no knowledge of what they might see except such suggestions as they had gotten in a hazy description of the property by an old neighbor, they started again at the shaft bottom, this time with cap lamps as well as candles. The main entry and the parallel "Durham entry"—so called because local tradition had it that miners from Durham, England, drove it—ran about 1,800 ft. up an approximate 5 per cent grade to a junction with main cross entries.

According to local history the cross entry on one side led into workings operated on shares by Welsh miners and the other into Durham territory. These two sets of co-operative coal operators were reputed to have scoffed at each others' skill as miners and to have maintained such keen rivalry that it periodically broke out in free-for-all fights both in the mine and outside.

Standing at the junction of the main heading with the side entries, it was evident to the three explorers of the mine that the two entries had been driven by

different types of miners. The Durham entry had been sheared on the right and shot from the left while the Welshmen—whether they were all left handed or not—had sheared on the left and shot from the right. The marks of skillful pick work were plainly seen on one rib of each entry and unmistakable drillhole traces on the opposite side. About 4 ft. of coal had been shot down at each fall.

NOT A NAIL OR BIT OF METAL IN CARS OR TRACK

Also standing at this junction, amid a collection of most interesting wooden construction—mine cars, tracks, slope-hoisting device and whatnot, all made without a single nail or bit of metal—it was easy for the three to get a general idea of the mine's main haulage. Loads had been brought in from both headings to the top of the main entry by animal power. Between there and the bottom gravity did the job.

A huge wooden bull wheel was originally mounted at the top of this 1,800-ft. grade. A single track ran from it down to the shaft, with a passing track at the half-way point. Obviously a load was lowered down the grade while an empty on the opposite end of a rope running around the wheel was drawn up.

The bull wheel is a rare piece of mechanism—one of

Bottom Layout of the Old Mine as the Engineers Found It

Old mines, of which examples may be found at Bostonia, near New Bethlehem, Pa., and near Shawmut, Elk County, in the same state being driven by mine workers of similar origin to those who worked at Miners Shaft, though at a slightly later date, show roadways just as meticulously perfect and track of somewhat similar character. Strap iron on edge, however, was used at the latter place in place of wood rails. This was notched and not spiked to the ties.

the rarest, probably, in American coal mining. Today it reposes cumbrously in the office of W. K. Kavanaugh, president of the Southern Coal, Coke & Mining Co., of

Displacing Air of Civil War Days

The engineers, anxious to enter the ancient mine, first built this little stack over the up-cast air compartment of the shaft, fired up the antiquated ventilating furnace 210 ft. below and awaited results. "It worked fine," says "Jack" Richmond, one of the adventurers. "In a minute the air flow was going strong." Soon they walked in—the first men to invade the place in the memory of the oldest settlers.

An Open Door Leading Direct to 1844

The mouth of Miners Shaft, and a peek down the shaft itself, four miles from Sturgis, in western Kentucky. Engineers entered it, descended 210 ft. and walked from today back into coal mining of long, long ago. There they found ingenious equipment lying just as it had been left two generations earlier.

St. Louis. Mr. Kavanaugh would like to put it in a historical museum if someone would convince him which one should have it.

The old wheel, about 56 in. in diameter, had broken down its wooden mounting, but it was intact. It is made of Southern gum and hardwoods of various kinds

Old-Time Hand Mining Was Accurate

This snapshot, taken by flashlight in an aircourse in the mine as it appeared after standing idle since before the war, gives some idea of the geometric exactness with which ribs were sheared with picks.

and shows the skill of woodworking craftsmen. Not a nail was used to hold it together; pegs and glue served the purpose. Flat 2x8-in. spokes were keyed with wooden wedges into a hand-hewn solid ash axle—an octagonal log 4 ft. long.

Fragments of a wooden brake which had been operated on one end of the axle were to be seen lying about. It was merely a long 12-in. plank cut in one edge to fit the bull-wheel shaft and hinged at one end close to the braking point so as to allow powerful leverage. A good idea of the construction of the old wheel can be gained from the accompanying photographs of it. The ends of the octagonal log axle were sawed off so that the big relic could be hoisted up the little shaft.

A half dozen ancient pit cars were lying about the place, their running gear gone, but their wooden bodies still stoutly mortised and tenoned together as shown in another illustration. Each car was 3 ft. 6 in. long and about 26 in. deep. Only a few sections of the all-wood track used in the mine before the Civil War were to be

found. The rest had rotted away. In the track, too, there was no sign of any metal. Ties about 6 in. square supported 2x4-in. rails set edgewise in notches and keyed with hardwood. At the turns rails were bent into curves that appeared to be in nearly perfect alignment in spite of their age. No trace of the switches could be found.

The underground adventurers spent parts of several days in the old mine, but because of the obstacles they encountered they never penetrated much deeper into the workings than the top of the gravity plane. Peering into necks turned from the main entries, they concluded that rooms had been driven to great lengths, but exact measurements were not made. Most of the coal appeared to be about 48 in. thick.

The history of the place as compiled by Mrs. Clarence R. Wilson, of Sturgis, links up the mine with long-ago politics. The property was owned and operated in 1860 by John Bell, the nominee of the Constitutional Union party, for President of the United States in that year in the four-cornered race against Lincoln, Breckenridge and Douglas. John Bell operated two or three other openings into that same seam of coal. Little was done with the property after the war because of a confusion of litigation.

In early days Bell coal was recognized as high-grade fuel for steamboats. The late Captain John Nelson, who died almost a centenarian a few months ago in his home near the property, used to tell of the historic race from New Orleans to St. Louis of the river steam-

Here Is the Old Bell Mine Bull Wheel

In the days "befo' de wah" it operated at the top of a gravity slope in a western Kentucky mine, long abandoned. J. A. Richmond, of St. Louis, who stands beside it, was one of three mining engineers who discovered it. The wheel, made without a single nail, is looking for a resting place in a museum.

What the Underground Adventurers Found

At the top of the gravity slope running 1,800 ft. from a junction of main entries down to the shaft bottom lay this collection of relics. Not a single nail was used in the construction of either the big sheave wheel or the little wooden cars, whose trucks had decayed with time. Wooden pegs and mortise and tenon joints were still tight. The object leaning against one of the cars is not a petrified, headless miner, but merely a slab of roof.

ers Natchez and Robert E. Lee, in which Bell coal played a part. The Lee, Captain J. W. Cannon, beat the better designed Natchez over the 1,252-mile upstream course by 3 hours and 14 minutes, taking Bell coal from a barge in midstream without stopping. The race is an epic of the Mississippi River, and the story of it once was much told around the three slope mines which grouped about the Miners Shaft.

Nothing else so spectacular ever happened in the history of this coal, but the output of the property is said to have maintained a good reputation as a fuel for metallurgical use in Civil War times and today part of it is used in gas manufacture. Some day it may be coked on a large scale if a large production is obtained.

REJUVENATION HAS BEEN BEGUN

The rehabilitation of the property, underground and on top, is beginning to convert the mines from potholes into real producers. Also it is giving the rolling mills around the top works something of the appearance of a forest park. An artificial lake lies in one of the little valleys, a small modern hotel for miners and a wide-porch lodge for company men perch on wooded hills, and winding roads add their contribution to the park effect. Modern engineering is having its way, top and bottom, in these mines, but nothing is going in that for picturesqueness can equal the old bull wheel that has come out and the old wheel's contemporary types of mine equipment which still lie where Davis, Richmond and Herbert found them, in "befo' de wah" surroundings.

The Miner's Torch

"Master Minds"

ON A diner between Cleveland and Washington recently I happened to be thrown with a lumberman and a clergyman. The lumberman remarked that his industry was the most misunderstood industry in America. "Why," said he, "the public seems to think that we are all robbers and crooks and they believe we are fighting the conservationist at every turn and playing fast and loose with the lumber reserves of the country. In fact the big men of our industry have become so worked up over the things that people are saying about us that they have raised a fund with which to carry on a national advertising campaign, the purpose of which will be to get the true facts about the industry before the public. In these articles no arguments will be advanced and no attempt will be made to draw conclusions. We will give only the facts and allow the public to draw their own conclusion."

Misery sure does love company! All these years I have been thinking that the dear public considered the coal industry the yellow dog of them all, and here comes a man willing to argue the matter.

I remarked that I was anxious to know what results they will get from their publicity as I had been thinking for years that the coal industry should make a similar investment. This brought the minister into the discussion. "Speaking of publicity," he said, "you must have noticed that we churchmen have been getting a lot of free publicity of late because some of our clergymen can't agree about the Creed, and now to cap the climax, as it were, I see by the *Literary Digest* that a New York newspaperman ridicules our profession as one that lacks the leadership of men with imaginations; in fact, is under the spell of second-rate minds."

How many times and in how many different places have I heard this same complaint made about the leadership of the coal industry! Give us leaders with imaginations and we'll sail through with flying colors is the cry at every important gathering of coal men.

Then I suddenly recalled a remark made by a professor in a history class while I was at college. "In looking back through the centuries you will discover that in each generation there are only a few brains that can be classed as first class," was about the way he put it. Think of it! Here I remembered a remark forgotten for twenty-seven years and recalled it when it was exactly what was needed to explain a paradox. Who says everything you learn in college is useless?

If there are only a few master minds in our generation why is it reasonable to suppose that they should all be found hooked up with the coal industry when the so-called learned professions can't attract their quota?

But if there are not enough first-rate minds to go around in our industry what's to hinder a lot of men with second-rate or even third-rate minds from getting busy and asserting themselves? Perhaps if they would, we would see an end to many of the problems in the lumber industry and the religious field and the coal industry; at least that is what we decided in the diner that night—the three of us.

Power Shovels Save Drudgery of Hand Mucking

Labor Scarcity Renders Mechanical Loading Necessary—Power Shovels Enable Bigger Cuts to Be Pulled and Obviate Blockholing—Specially Designed Rock Cars Facilitate Tunnel Driving—Splitting Trick Would Speed Work

DEVELOPMENT tunnels driven in the Pottsville district and Schuylkill Valley of Pennsylvania in most cases are either 7x10 or 8x12 ft. in cross-section. In a 7x10-ft. tunnel the quantity of rock brought down at a single blast approximates 50 tons. In the past all this rock had to be loaded out by hand labor during an 8-hour shift.

In order properly to appreciate what has been accomplished by power shovels in the way of rock mucking in the anthracite fields conditions existing prior to their installation should be considered. Many types of mechanical loaders had at sundry times been employed in this work, but for various reasons all had proved unsuccessful. Of course some were tried out before they had been perfected as they are today, while others were totally inadequate to the work in hand.

In making a 6-ft. cut in a rock tunnel 8 or 9 cars of rock would be shot down, each car having a capacity of 127 cu.ft. The loading of this rock by hand methods was about all that one gang of muckers could do in a shift. Such a gang was composed of a muck boss and 4 or 5 laborers. In some instances, of course, one gang might handle as much as 12 or 13 cars, but this performance was exceptional. Only after much persuasion, and then only occasionally, would the men handle more than the customary 8 or 9 cars per shift.

SOMETIMES THE MUCKERS FLATLY BALKED

In not a few cases they would refuse to handle the muck at all after they had sized up the pile and concluded that it contained, say, 12 to 14 carloads. Naturally if the muckers refused to work, the drillers lost the succeeding shift. As a logical result the drillers on the next shift would reduce the depth of holes drilled so as to decrease the rock brought down to a quantity that would suit the muckers. This, of course, reduced the average depth of cut pulled.

Measured over a period of two months, the depth of cut pulled by different operators averaged from 5 to 6 ft. The extreme independence of the mucking crews, of course, was traceable to a shortage of the kind of men who were willing to engage in this arduous work. Naturally, but few of these crews could compare with what the old timer knew as hard-rock muckers. Though some gangs were admittedly fairly good they were exceptions to the general rule. Throughout the anthracite fields most men preferred to engage in labor that was easier, even though they were paid lower wages for doing it.

POWER SHOVEL RELIEVES ACUTE LABOR SHORTAGE

The conditions outlined became so acute during 1923—throughout August and September many development tunnels were idle for lack of men—that it became obvious that some means other than man power must be found to load the muck. Early in the year, therefore, one of the largest operators in the Pottsville region installed a power loader for this purpose, the Hoar shovel being the type chosen. The tunnels in this

company's mines are 7x10 ft. in cross-section and are driven fairly level, only sufficient grade being given them to provide drainage.

The accompanying time study is typical of present-day performance of these shovels although on the particular day when this study was made conditions were more unfavorable to the machine than usual. This was due to two reasons: First, because the muck had been scattered further by the blast than usual and, second, because the muck crew on the preceding shift had failed to carry the track forward in proper shape.

In this instance, as in most cases, a single track of 42-in. gage was carried in the tunnel. The cars used in the run to be described stand 4 ft. above the rail and are 4 ft. 7 in. wide and 8 ft. 4 in. long. They are special rock cars built solely to serve the mechanical loaders and were developed by the coal-company engineers. A switch is placed from 250 to 350 ft. away from the working face. Mules haul the cars to the shaft, which is about 1,500 ft. distant.

TABLE I—RELATIVE PERFORMANCE IN HAND AND ROCK MUCKING

	Hand	Machine
<i>Colliery "A"</i>		
Cuts mucked.....	70	24
Feet driven.....	403	169
Feet per cut.....	5.76	7.04
Cost per cut.....	\$25.00	\$16.68
Cost per foot.....	\$4.34	\$2.37
<i>Colliery "B"</i>		
Cost per cut.....	\$33.00	\$15.79
Cost per foot.....	\$6.19	\$3.40

It will be noted in this time study that 41½ minutes was consumed in loading car No. 1. This total loading interval is made up of 24½ minutes of loading time and 17 minutes of time consumed in moving the shovel. The reason for this movement of the shovel was the scattered muck to which reference has been made. At no time during the loading of this car was the muck more than 6 in. to 1 ft. deep. From this the importance of keeping the muck close to the face will be appreciated at once.

Some drillers succeed in loading their holes so thoroughly in accord with existing conditions that they rarely scatter the muck any great distance from the face. In the case of car No. 2 the muck was still thin, this being shown by the number of moves made. Each move of the shovel means an advance of 5 ft. into the muck pile so that the total distance from the face to which the rock was blown in each instance readily may be approximated.

Switching time on each car varies from 4 minutes to nearly half an hour. Therefore it will be readily appreciated that the total time required for cleaning up a face could be greatly lessened by reducing the delay arising from this cause. It should be borne in mind, however, that this mucking crew, consisting of the machine runner, a laborer and a miner—the latter is responsible for the safety of the other two—is paid for a full 8-hour shift and that consequently speed in mucking is not of great importance to them so long as they get the cut cleaned up, the track laid and make all

Mechanical Shovel Loading Rock from Open Cut

Shoveling rock that has merely been blasted loose is hard work whether done by hand or by machine. This illustration shows a Hoar shovel working in a rock cut. The operation of this machine is much like that of a full-revolving steam shovel although its size, of course, is much smaller. By the use of shovels of this type in rock tunnels underground, blockholing, or the blasting of pieces of rock already shot down, has been entirely obviated, the machine successfully handling even the largest pieces.

other provisions for the next shift. Under advantageous conditions, as may be judged from this time study, this is easy of accomplishment.

It will be noted from this time study that although it required a total of 6 hours 11 minutes to clean up the shot, only 2 hours 46½ minutes was actually consumed in loading cars, and that of this 24½ minutes was taken up in loading the first car leaving practically 2 hours for loading out the rest of the muck. Switching caused a delay of 2 hours and 23 minutes and moving the machine entailed a delay of 32 minutes.

In contract work outside the mining regions where speed is a prime requisite rock blasts are being loaded out in a 4-hour period. This, however, means a split trick for the muck crew, which is not being used so far as is known in any anthracite mine. It is, however, being utilized by some contractors in tunnel work elsewhere.

Comparing operation of the power shovel with hand labor in tunnel driving in two separate collieries we have the results shown in Table I.

It will be observed that in colliery A the average length of cut made was 1.28 ft. greater than that obtained when hand mucking was employed. Only 5 hours 49 minutes of the 8-hour shift was actually consumed in mucking operations. It is obvious that muck from a heavy cut can be more advantageously and quickly handled if it lies close to the face. All data set forth refer to 7x10-ft. tunnels.

HIGH ROCK CARS INTRODUCE DIFFICULTIES

In considering the mucking of 8x12-ft. tunnels somewhat similar conditions are encountered, except that in most cases the cars to be filled are much higher, sometimes standing as much as 5 ft. 6 in. above the rail. The standard model shovel will not load these cars except in one end, so that a special form of this machine loader has been designed for this work. This was developed primarily for use in the anthracite mines of Pennsylvania. Basically it is the same as the standard model. Its frame, however, is higher and heavier.

Some coal operators have developed special rock cars for use in mucking and allow 12 of these cars to each

shovel. This arrangement, of course, necessitates that these cars be hoisted separately from the coal cars so that they may not be mixed with them. The many advantages resulting from the use of cars intended especially for the handling of rock more than offset the trouble on the surface entailed by their use.

Where cars from 5 ft. to 5 ft. 6 in. high are used in a 7-ft. tunnel it is extremely difficult to build a shovel that will load them to capacity. This is because such a high car leaves so little room between its top and the roof. A hand shovel might be introduced into the space left available, but this space is extremely small for the introduction of any mechanical means of loading.

HARD WORK IN MUCKING IS NOW GONE

Through the introduction of the power shovel, blockholing has been entirely eliminated. No pieces are now blasted from the face that the shovel is unable to load, even though some of them weigh up to a ton. After a cut has been mucked out the shovel is withdrawn by a mule or locomotive and placed on the aforementioned switch located several hundred feet from the face, ready for the firing of the shots.

Power shovels have taken all of the hard work out of rock mucking. Since their introduction it has become difficult to find a hand shovel anywhere about the rock workings when one is needed in order to do a little cleaning up at the face.

TABLE II—TIME STUDY OF ONE DAY'S SHOVEL OPERATION

Car No.	Switching On	Switching Off	Moving Cars to Shovel	—Loading Cars— On	Off	Time	—Moving Shovel Forward— On	Off	Total Time per Car

Last car cleaning up face (3 minutes taken up picking down loose rock in face). Total time to clean up cut including all delays 6 hours 11 minutes. Total switching time 2 hours 22½ minutes. Total time loading cars 2 hours 46½ minutes. Total time moving shovel into muck 32 minutes. On this cut much delay was caused by track being torn up and not replaced. This was an exceptional condition, not encountered under ordinary working conditions. Total weight of rock handled, about 48.6 tons. First car cleaning up scattered muck; muck very thin.

Best Shop Practices in Cutting and Tapping Machine Threads for Repair Work

Preparing the Material Before Cutting the Thread—Use of the Stock and Die—Tapping Threads in Different Metals—Sharpening the Tools

BY GUSTAV H. RADEBAUGH
Mechanical Engineer, University of Illinois, Urbana, Ill.

A TAP is a hardened, highly tempered steel tool for cutting internal threads and has a thread and flutes cut in it to give cutting edges. The blacksmith tap is tapered $\frac{3}{4}$ in. to the foot. It is used on tapping jobs where it is not necessary to maintain a standard. The set of machinist's hand taps, Fig. 1, A and B, are not tapered but maintain one size from the first thread to the last.

Of these two styles of taps many different sizes are made. Ordinary taps run in various sizes in steps of sixteenths, but taps one sixty-fourth or one thirty-second oversize also can be bought. The hole for a tap should be drilled of a diameter equal to that of the bottom of the thread. Some taps have marked on the shank the size of drill that should be used in drilling the hole for tapping.

The pipe tap, Fig. 1, C, is used for cutting pipe threads. The threads of pipe, which are different from those for machine bolts and machine screws, are made according to two standards, the Briggs and the Whitworth, the first being that more commonly used. A tap wrench is used for turning the tap in the hole. When tapping cast iron, oil is not needed, but in tapping steel a good fatty oil should be used. The die and die stock, Fig. 2, are used for cutting threads on bolts and screws. A die stock is furnished for each size of thread. The standards for die blocks are the same as those for taps. Thread standards always cause more or less difficulty because of the great number of sizes and designs. Thus the machine-bolt standard differs from that used for the threads employed in automobile construction. A common standard for $\frac{1}{4}$ -in. bolts is twenty threads to the inch; for $\frac{3}{8}$ -in. bolts, sixteen threads to the inch and for $\frac{1}{2}$ -in. bolts, twelve or thirteen threads to the inch.

Cutting Threads with Die and Tap.—On repair jobs, when fitting bolts, nuts and screws, the operative sometimes has difficulty because he does not fully appreciate the importance of thread standards. The pitch of a screw is the number of threads to an inch, and it is important when fitting a screw to know that the number of threads on the screw and in the job are the same.

In this country extensive use is made of the United States Standard thread, which can be identified by a

flat on the thread points. The V-thread, which is in the shape of a V with a 60-deg. angle, can be identified by the thread coming to a sharp point. There are one or two other styles of threads, but those already mentioned are the more commonly found. The shapes of the V-Standard, Whitworth Standard, United States Standard, Acme Standard, British Association Standard and Square Thread are shown in Fig. 3.

The number of threads per inch for bolts and nuts such as are used on mining machines usually conform to the United States Standard. This standard is shown in Table I. For bolts and screws used on automobile construction the American Society of Automobile Engineers some years ago adopted a standard which may be identified by its fine pitch. For instance the S.A.E. thread for a $\frac{1}{2}$ -in. bolt is twenty threads per inch. This standard has the U.S.S. form of thread.

For the convenience of the trade all tap and die manufacturers mark on the tool the standard number of threads per inch, size of thread, and sometimes indicate on the tap the size of drill which should be used to provide the hole for tapping.

When taps and dies are used to cut steel they must be lubricated. A good grade of animal lard oil, sperm oil or a mixture of graphite and tallow—10 per cent graphite and 90 per cent tallow—are the best lubricants to use when tapping or threading steel or iron. A good

TABLE I—TAP-DRILL SIZES FOR U. S. STANDARD BOLT THREADS

Diameter of Bolt, In.	Threads per Inch	Size of Tap Drill
$\frac{1}{8}$	20	No. 7
$\frac{5}{16}$	18	$\frac{1}{4}$ in.
$\frac{3}{8}$	16	$\frac{5}{16}$ in.
$\frac{7}{16}$	14	$\frac{27}{64}$ in.
$\frac{1}{2}$	13	$\frac{27}{64}$ in.
$\frac{9}{16}$	12	$\frac{31}{64}$ in.
$\frac{5}{8}$	11	$\frac{17}{32}$ in.
$\frac{3}{4}$	10	$\frac{21}{32}$ in.
$\frac{7}{8}$	9	$\frac{49}{64}$ in.
1	8	$\frac{7}{8}$ in.
$1\frac{1}{8}$	7	$\frac{63}{64}$ in.
$1\frac{1}{4}$	7	1 $\frac{1}{8}$ in.

Figs. 1 and 2—Taps and a Machinist's Set
The upper figure shows untapered sets at A and B and a tapered set at C for pipe threads. In the lower figure is a popular set of taps and dies.

Fig. 3—Standard Screw Threads

Much confusion and difficulty often is experienced by the use of different styles and types of threads. Manufacturers of mining equipment can do much in the way of standardization and thus help to keep the equipment in repair.

soap compound is better than a mineral lard oil. Machine oil is a poor lubricant for thread cutting. When tapping cast iron, oil should be used sparingly, for it causes the chips to stick to the flutes of the tap.

If a hole is to be drilled for tapping, it is important that a drill of proper size be used. This can be determined by finding the diameter of the tap or bolt at the bottom of the threads or by referring to a chart of tap-drill sizes such as is shown in Fig. 1.

In threading soft steel by hand with the hand stock and die, the end of the material to receive the thread should be beveled, as in Fig. 4; that is, the sharp corners should be removed at an angle of about 45 deg. This can be done by using the coarse, or bastard, file, as shown in this illustration. This operation is important, for when it is done it makes it easy to start the die and enables it to do its work without injury. The threads also will be cut more correctly.

The end of the stock may be rounded, before cutting the thread, by the use of a hammer, as shown in Fig. 5. The end of the stock is struck medium hard blows with the hammer, the stock being held in about the same position as if it were being drawn to a point. To do this the stock need not be heated.

Fig. 4—Preparing the Material for Threading

The end of a piece of rod to be threaded is filed, making the work much easier, more rapid and indeed more nearly correct also.

Fig. 5—Shaping Rod for Reception of Die

This may be done without heating the material. It will enable the operative to cut a straight thread. The stock to be threaded is held while being shaped as if it were being drawn to a point and is usually done to assist starting the threads.

Dies are divided into two classes: Those which must pass over the thread several times in the cutting of the finished thread and those that complete the thread in one cut. In the latter class there are adjustable, spring and solid dies. They are made from tool steel and tempered very hard.

A die can be sharpened by grinding back the front face of the cutting teeth or chasers. Adjustable and spring dies are best suited for general repair work. When cutting a thread, the die block is held in a die stock, one of these stocks serving for several sizes of dies. As the die is not suited for reducing the size of the stock being threaded it is bad practice to use a standard-size die to cut threads on stock that is rolled $\frac{1}{8}$ in. oversize.

To cut the thread the piece to be threaded is placed in the vise with the rounded end up. The die is placed on the bar and with a downward twisting or turning motion it is forced on the stock, as shown in Fig. 6. After two or three turns forward the die should be given a slight turn backward. This enables the operative to remove the cuttings and allows the oil to find its way to the points of the cutting teeth. If a full thread up close to a shoulder is desired, the die is

Fig. 6—Using the Stock and Die

Many thread-cutting sets permit of slight adjustment; this aids materially when repair work is being done.

Fig. 7—Adjusting the Die

Slight variation in the threads in a nut are frequently annoying but are easily remedied with an adjustable die, which may be set to cut over- or under-sized threads.

turned over and the cutting operation is continued up to the shoulder. Dies are made for right- or left-hand threads. When using a left-hand die it should be turned counter-clockwise.

When cutting a thread with an adjustable or spring die, the size of thread always should be tested with a standard tapped nut. The die may then be adjusted, as shown in Fig. 8, by using a screwdriver. The designs of adjustable dies are such that this adjusting is simple and can be made quickly. The adjustable die can be altered as much as $\frac{1}{2}$ in. over or under the size marked on its side. The spring die will adjust about $\frac{1}{8}$ in. over or under size, but it is bad practice to extend this adjustment beyond these limits.

Tapping a Hole.—The tap is a tool used to produce internal threads. Hand taps are listed in sets, three taps comprising a set; the taper, plug and bottom taps. The taper tap is best suited for starting tapped holes. It can not be used, however, for completing a job unless it will pass clear through the work. The plug tap, which has the first three teeth tapered off, makes a full thread nearly to the bottom of a hole. The bottom tap is used to extend this full thread to the very bottom.

Fig. 8—Tapping a Hole

The secret of not breaking the tap in this operation lies in exerting the same effort at all times on both handles, unless this is done a slight side strain will break the tap.

It should be used after the plug tap to avoid breakage.

This tap is the best to use for all-around work. It must be understood that to get a hole tapped the proper size it is not necessary to use all three of the taps in a set. In Fig. 8 is shown the correct position for tapping a hole. The secret of proper tapping is to equalize the effort expended on the handles of the tap wrench.

How to Remove a Broken Tap.—Fewer taps will be broken if the proper lubricant is used. When a tap is broken near the surface of the metal it is cutting it can be removed easily by driving on both sides, as shown in Fig. 9. By doing this the tap is not wedged against one side of the hole as when using one drift, but the tap is forced to rotate.

Another method of removing broken taps is by heating the part containing the broken tap in a forge fire or with a gasoline blow torch, thus softening the steel tap. It is then drilled out. Injecting into the hole a solution of nitric acid—one part acid to five parts water—also has proved effective. The action of the acid on the steel loosens the tap and it can then be backed out by using a drift punch or a pair of pliers. The

Fig. 9—Removing a Broken Tap by Drifting

This is one of the simplest methods for removing a broken tap. By wedging up on both sides at the same time the tap usually can be removed.

Fig. 10—How to Determine a Thread Size

Gages similar to the one in this illustration should be part of every machinist's repair kit. This is the only sure way to correctly determine the pitch of the thread.

Fig. 11—Determining the Thread Pitch

The best way to determine the pitch of a thread is by the use of a gage, the pitch being marked on the side of each blade. The method shown here is not so accurate for determining the pitch of the thread because it is easy to count the threads incorrectly.

British Co-operative Coal Trade Making Giant Strides

Dominates Market in Some Cities—Private Dealers
Almost Eliminated in Places—Movement Gained
Impetus from War-Time Control

BY WILLIAM NOTZ

Washington, D. C.

AT THE present time a complete change is taking place in the coal business of Europe due to the increasing activities of co-operative consumers' societies. The trade in household coal is affected primarily. The movement is gaining such rapid headway that in several of the leading coal-consuming countries co-operative societies have already become the largest coal distributors. In a number of large cities they practically dominate the local market; in others they have developed into formidable competitors of the private coal dealers, and in a few cases have well-nigh eliminated the latter altogether.

One of the main objects of these societies is to bring the consumer as close to the producer as possible and thus eliminate the middleman's profit. They do not aim at making profit. While they sell their goods to their members for cash at the prevailing market price, all profits are ultimately returned to members in proportion to purchases in the form of dividends. These organizations gradually branched out from selling and went into the field of manufacturing. More recently they have been evolving plans to acquire and control the most important of the raw materials that enter into the production of the chief necessities of life, such as foodstuffs and coal.

CO-OPERATIVE MOVEMENT WIDESPREAD IN EUROPE

It is astonishing to observe what a large proportion of the population of European countries is linked up with the co-operative movement. In England about fifteen million persons are affiliated with such societies through some member of each family. In Scotland more than half of the population, and in Germany approximately three million families purchase a large part of their

acid remaining in the hole should then be washed out.

To find the number of threads per inch on a bolt or in a nut the screw-pitch gage is used as shown in Fig. 10. This gage has a number of thin blades on which are cut two or more teeth, the distance between which corresponds to the distance between two threads on a screw of given pitch, the number of which is stamped on the blade. By a comparison of the threads on the bolt with a selected blade from the screw-pitch gage the exact pitch of the bolt can be determined. On some of the coarser threads the rule is used as shown in Fig. 11. This is not an accurate method, but it proves helpful in finding thread pitches.

COMMON THREAD PITCHES CAUSE CONFUSION

Often in fitting a $\frac{1}{2}$ -in. bolt with nuts it is found that the nut will not screw on the thread, even though the diameter indicates that it is of correct size. By measuring the threads per inch on the bolt and in the nut you may find a 13-thread nut and a 12-thread bolt. There are two common thread pitches for $\frac{1}{2}$ -in. stock, namely 12 and 13 threads per inch. This fact frequently causes confusion.

necessities from co-operative shops. According to the latest estimate there are fully thirty million persons accredited members of co-operative organizations in different parts of the world, and the movement is growing steadily.

While the co-operative system of distribution has been in operation for nearly a hundred years in parts of Europe, the sale of coal on a large scale by wholesale and retail co-operative societies is of comparatively recent date. It is largely an outgrowth of war-time conditions. When the government assumed control of necessities of life in England and Germany, food and fuel controllers eagerly seized upon the excellent distributive organizations that the thousands of co-operative societies had built up. In Germany there are at present about 50,000 co-operative societies and in the United Kingdom approximately 1,400. Each society operates a number of retail establishments, and like a vast network of chain stores these organizations spread out over city and country and link together hundreds of thousands of families and millions of consumers into one organic entity.

SOCIETIES EXPANDED AFTER THE WAR

When war-time control ended, the success that co-operative societies had achieved in the handling of coal prompted them to continue and expand that line of business along with other commodities usually dealt in such as foodstuffs, clothing and household articles.

English Co-operative Wholesale Society.—The English Co-operative Wholesale Society led the way. It probably is the largest organization of its kind in the world. The co-operative retail societies of England, Scotland and Ireland have each a wholesale organization of their own. The largest of the three is the English Co-operative Wholesale Society, popularly known as the C.W.S. Its headquarters are at Manchester. It has more than 50,000 employees and the value of its wholesale distributive trade amounts to about four hundred million dollars per year. It owns and operates more than a hundred manufacturing plants, and proudly styles itself "The largest democratic trading institution in the world."

The C.W.S. has divided its coal business into three

districts, centering in Manchester, Newcastle and London. The general supervision rests in the hands of the board of directors of the C.W.S. at Manchester. Each of the district coal offices is in the hands of a district manager. The C.W.S. sells only to its own registered retail societies, no sales being made to outsiders or non-members. This is required by the Industrial and Provident Societies Act of 1893, under which the English co-operative societies operate.

Not all retail co-operative societies purchase their coal supplies exclusively from the C.W.S. In the London district only two give all their coal trade to the local wholesale office. The others distribute their purchases about 50-50 between the C.W.S. and private dealers. The largest co-operative retail society in London buys about 40 per cent of its coal from the C.W.S. But on the whole the various retail societies are steadily buying larger quantities from the C.W.S. Aside from other reasons, many are prompted to do this because the C.W.S. has on numerous occasions when a coal shortage occurred, taken good care of its loyal customers. Besides, it has made it a point to furnish good coal at as low a price as possible.

The distribution of coal in the Manchester district alone amounts roughly to one million tons a year. All three districts together annually handle approximately two million tons. Of this total about 90 per cent goes for domestic consumption and the rest for industrial purposes.

C.W.S. OPERATES ITS OWN COLLIERY

In line with the general policy of the International Union of co-operative societies regarding the control of raw material, the C.W.S. has already taken active steps to mine its own coal. Several years ago it purchased valuable undeveloped coal fields in Yorkshire, which it contemplates developing at an early date. Moreover, in 1917 it purchased the Shilbottle colliery, in Northumberland, which will have a weekly output of 7,000 tons after repairs now under way shall have been completed. The entire mine is being electrified.

In the absence of large collieries of its own the C.W.S. purchases its supplies on the coal exchanges of London, Manchester, Leeds, Birmingham and Newcastle. The district managers do the buying and deal with the pit masters at the exchanges. It is not customary to purchase on long-time contracts. Shipments by rail and water are made directly from the pits to the yards of the retail societies in quantities varying from a few carloads up to a thousand tons.

In addition to the railroad and colliery coal cars used for transporting its supplies, the C.W.S. owns coal cars of its own. The London district operates 712 cars or wagons carrying from 8 to 12 tons each. The Manchester district owns 130 coal cars. For these wagons the C.W.S. charges the current coal freight rate to the retail societies. At the rate obtaining at present this nets a handsome profit to the C.W.S., which it turns over to the shareholders, the retail societies and their members in the form of dividends.

The London district coal office of the C.W.S. stands well at the top in the general wholesale trade of domestic coal in that metropolis. It is under the efficient management of A. E. Cockbaine, who is a practical coal man and has been connected with the co-operative movement for 25 years. The membership of the London co-operative retail societies is so large that if they were to act as a unit through the London office of the C.W.S.,

they might readily become the controlling factor in that large consumers' market.

The co-operative societies in Plymouth (with a membership of 50,000 and a coal trade of 80,000 tons per year), Leeds and Edinburgh (the latter with a membership of 62,000) hold a similar commanding position in relation to local coal prices.

From 350,000 to 400,000 gross tons of domestic coal are handled annually by the London office. The average handling cost for the London district amounts to but 3½d. (7c.) per ton. Prior to the world war the gross profit for this district averaged 3d. (6c.) per ton. The above figures do not include the industrial coal handled.

Scottish Co-operative Wholesale Society.—The Scottish Co-operative Wholesale Society, Ltd. (S.C.W.S.), Glasgow, serves a similar function for the retail co-operative societies in Scotland. It is the largest dealer in house coal in Scotland and purchases domestic coal for upward of 200 depots in Scotland, besides industrial fuel for about 20 mills and works. Its coal department had a turnover in 1922 amounting to 283,552 tons of household coal. This was an increase of 41,852 tons over the previous year. The society paid for it at the mines a total of £304,281. The mills and manufacturing works of the S.C.W.S. during 1922 used 45,430 tons of coal as fuel.

While the English C.W.S. sells only to its registered retail member-societies, the S.C.W.S. sells also to private parties who are not members of a local co-operative society. But such orders must be sent in to the S.C.W.S. through a local retail member society. The S.C.W.S. owns 115 coal cars, of which several are hopper-bottomed and of 30 tons capacity.

St. Cuthbert's of Edinburgh.—St. Cuthbert's Co-operative Society of Edinburgh, though otherwise affiliated with the S.C.W.S., carries on an independent coal trade and is the biggest coal dealer in Scotland's capital, doing 75 per cent of the local coal business. It is the only consumers' co-operative society in Edinburgh and has a membership of 62,000. This society is considered by many to be one of the best operated in the world. Thomas Young is its manager.

BUYS COAL DIRECT FROM COLLIERIES

In 1922 the coal sales of St. Cuthbert's amounted to 130,000 tons. It buys its coal directly from the collieries and transports it in its own cars, of which it has 260 of 10 tons capacity each, to its coal yards in Edinburgh. The society operates 7 coal yards from which deliveries are made by its own lorries.

The total distributive expense is 8s. per ton from the railroad car to the consumer's bins. This covers all expenses, including feeding and shoeing of horse, veterinary charges, stable expenses, coal bags, depreciation, etc. The fact that the members of St. Cuthbert's live in close proximity to one another makes long delivery routes unnecessary and gives the society an advantage over private coal dealers.

ONLY A THIRD OF THE TIME GOBBING ROCK.—Mr. Brosky points out that in the article "With Hand Shoveling 10 Tons per Man and 26 Tons per Loader Already Attained," in the issue of *Coal Age* of Feb. 7, on page 202, it is stated that "At least two-thirds of a loader's time is utilized in gobbing the parting." In justice to him it should be stated that this was a printer's error and should read "At least one-third, etc."

News Of the Industry

Miners and Operators Agree to Renew Old Contract for Three Years

Special Dispatch to Coal Age

SCALE IS RENEWED

Late Monday, February 18, the present bituminous wage scale was approved at Jacksonville, Fla., for a term of three years by the unanimous action of the sub-committee of miners and operators of the Central Competitive Field.

In their second caucus last week the operators withdrew their former proposal for an indefinite wage reduction, and gave most of their time, according to Phil Penna, of the Indiana Operators' Association, to discussion of the miners' request for a four-year contract until they adjourned until the joint meeting with the miners the following morning. According to Penna, a motion was made for a return to the 1917 wage scale, which would mean 24c. a ton reduction for tonnage men and \$2.50 a day reduction for day men. There was no discussion of this motion.

DISCUSS DISTRICT SETTLEMENT

Considerable time was devoted to discussion of a proposal that the prospective joint wage agreement be made effective by districts, subject to settlement of internal differences, instead of in the entire Central Competitive Field at once. This would mean that separate districts might determine conditions and defer action on the wage agreement until district conditions were settled satisfactorily.

The sub-scale committee of operators and miners threshed over the question of a one-year or a four-year wage contract for four hours on Feb. 13 and adjourned without reaching any understanding.

Following adjournment Phil H. Penna declared that while nothing had been definitely settled there will be no strike April 1. "In my judgment," said he,

"there is not a possibility of a strike. Both sides realize that a process of elimination through the operation of economic laws is the only salvation."

The deliberation virtually came to a standstill on Thursday while the operators argued their differences and tried to agree on a contract term they would sign. The miners demanded that they sign for four years.

The operators agreed to a renewal of the wage scale, it was learned definitely, and are united in opposing the miners' request that "internal conditions" be referred back to the districts for solution in district joint conferences.

Operators of steam-coal mines are said to be willing to sign for three years, but some representatives of independent mines in western Pennsylvania declared opposition to anything longer than one year, it was reported.

Prosecution Decides to Put Keeney on Trial First

A surprise was sprung when the state elected to try C. F. Keeney, president of district 17, United Mine Workers, instead of William Blizzard, president of subdistrict 2, on the indictment from Logan County charging Keeney and others with being accessories before the fact in connection with the murder of John Gore, a Logan County deputy sheriff, at the time of the "armed march" of 1921. The cases against the union leaders were called in the Circuit Court of Fayette on Feb. 11.

The defense at the opening of the trial offered a number of special pleas, all revolving around the main contention that the defendant had not been brought to trial within three terms of court except in specified instances where continuances had been obtained by the defense. Prosecuting Attorney Love pointed out that three terms within the meaning of the law had not passed and alluded to the fact that most of the intervening terms were accounted for by changes of venue which carried the cases successively to Jefferson, Morgan and Greenbrier counties. It was contended by the defense that a default entered at one of the terms in Jefferson County covered only specific ones, the state holding that it covered all the indictments. Judge J. W. Eary supported the contention of the prosecution.

Nova Scotia Strike Ends; Miners Get Increase

The strike of the miners of the Dominion Coal Co., subsidiary of the British Empire Steel Corporation, in Nova Scotia, was ended on Feb. 11 when an agreement for one year was signed by representatives of the company and the United Mine Workers, at Montreal. The agreement, which is retroactive to Jan. 16, provides for the following increases over the rates in effect on Jan. 15: Datal men underground 30c. per day; datal surface men 25c. per day; shooters, loaders and contract men, including helpers, 7c. per ton; hand-pick miners, 8c. per ton; local contracts, 6 per cent.

It is estimated that the increases will involve an additional to the payroll of the 12,000 miners of over \$1,000,000 annually. The price of domestic coal supplied to the miners is increased from \$2.25 to \$3.60 per ton. Instructions were wired to the miners to return to work.

At numerous meetings held by the locals of the United Mine Workers of the Nova Scotia coal fields on Feb. 12 to consider the agreement made by their representatives with officials of the British Empire Steel Corporation, it was decided not to resume work until a referendum had been taken. Those opposed to acceptance of the terms agreed in contending that the increase in the price of domestic coal to miners from \$2.25 to \$3.60 per ton, largely wipes out the wage increases granted.

There also is some resentment against the order wired from Montreal to return to work on the ground that their representatives exceeded their authority in ordering a resumption of work before a referendum had been taken. On the morning of the 13th the whistles blew for work, but there was no response except at Dominion No. 1 Colliery, where the local had voted to return to work.

R. M. Wolvin, president of the British Empire Steel Corporation, signed the contract for the corporation; W. Dalrymple and Andrew Steel for the union. Silby Barrett and Robert Baxter signed the agreement for the Nova Scotia miners. Sir Newton Moore and F. W. Gray signed as witnesses.

The British Empire Steel Corporation regards the agreement reached as satisfactory in that it covers in more detail contracts previously entered into with the union, particularly as affecting working conditions in the collieries. It is hoped that an improvement in operating conditions at the mines and a more thorough understanding between the two sides will result.

"Exact Cause Not Definitely Known," Says Shanktown Explosion Jury

Inspectors Declare Source to Be Arcing of Rheostat of Mining Machine, Burning Gasket and Firing Gas and Causing Dust Explosion

A jury selected by Dr. A. H. Stewart, Coroner of Indiana County, to inquire into the cause of death of thirty-six men who lost their lives in the Lancashire mine at Shanktown, Pa., on Jan. 26, returned the following verdict:

"That on Jan. 26, 1924, about 3 o'clock p.m., in Lancashire Mine No. 18, located at Shanktown, Green township, Indiana County, Pa., the deceased miners came to their death as the result of an explosion of gas in said mine. The exact location of the origin of the explosion and the exact cause of said explosion is not definitely known." The inspectors who conducted the investigation and several miners who escaped following the explosion gave testimony.

The inspection commission appointed by J. J. Walsh, State Secretary of Mines, consisting of T. J. Lewis, Nicholas Evans and Thomas S. Lowther, inspectors of the twelfth, twenty-fourth and twenty-fifth bituminous districts, respectively, gave somewhat different testimony. Their report follows:

"The mine is a slope opening, mining the B, or Lower Kittanning, seam of coal, and is driven in a distance of about 5,700 ft., with an average dip of about 5 per cent. The system of mine development is with four main entries, the two center ones being used as inlet airways—one of them as a haulage road and the other as a traveling way—the two other entries, one on the right and the other on the left, being used as return airways. Flat mains are driven to the right and left from the main-slope entries and room entries are driven off the flat mains.

"The ventilation is produced by a 7x3-ft. reversible fan, driven by a 75-hp. motor using a.c. current, which operates as an exhaust and runs at a speed of 210 r.p.m., producing 75,000 cu.ft. of air per minute and a 2.5-in. water gage.

"On our examination of the record books of the mine foreman and fireboss, we found that on several occasions explosive gas had been reported at the face of one or more of the live entries, the reports showing that gas was being emitted in all the development entries that were being driven at the time the explosion occurred.

"All the live workings below No. 6 right flat were being worked with closed lights, the miners and daymen using electric cap lamps and the mine officials, shotfirers and machine runners using flame safety lamps for gas-testing purposes. The coal above No. 6 right flat is exhausted, and No. 6 right soon will be worked out.

"The employees in No. 6 right flat were using open lights, as explosive gas was never known to have been emitted in this section of the mine. It was ventilated by an independent inlet air current from an opening to the

surface on the right side of the mine above No. 6 right. After the explosion occurred all the employees in this section escaped safely to the surface through this opening, except one, who ran out to the main-slope haulage road and died from the effect of afterdamp.

"We entered the mine on Wednesday morning, Feb. 6, by way of the main-slope haulage road and proceeded with our examination of the conditions caused by the explosion until we reached the water near the face of main-slope entries. We found accumulations of explosive gas in these entries, but did not find any evidence to show that the initial point of the explosion had been at the face of the main slope.

"We then proceeded to No. 7 left flat and carefully examined conditions along the flat entries, room entries off the flat and also the rooms that were working in this section. We found some accumulation of explosive gas in all working entries and some of the rooms in this section. Thence we traveled into the No. 8 right flat section and worked until late in the afternoon without completing our investigation.

"We resumed our inquiry on the morning of Feb. 7, proceeding directly to the workings in No. 8 right flat.

"We found a closed-type electric mining machine at the face of the airway of that heading. This airway was being driven back and outward. Here canvas had been used to direct the air current to the working face. The machine was placed against the face of coal in position for undercutting. Explosive gas had accumulated in these flat entries.

"We also found a closed-type mining machine at the face of the airway of No. 1 butt room entry off No. 8 right flat. At these faces also explosive gas had accumulated. In this airway we found evidence of intense heat and much force developed outward, and this, connected with other evidence obtained, indicated that this had been the initial point of the explosion. The mining machine at the face of this airway had just completed the undercutting of the coal, and the machine was being re-

placed on the truck, to be moved to some other place, when the explosion occurred.

"By carefully examining this machine, we found evidence that caused us to suspect that defects in the electrical parts of this machine had caused the explosion. By dismantling parts of it, we found that an arc had occurred in the rheostat which caused intense heat and burned out the gasket between the frame of the machine and the plate by which the rheostat was covered. This gasket was consumed for a distance of about 6 in. This burning of the gasket would allow the flame to pass upward into the atmosphere.

"The whole machine must have become charged, and arcing possibly may have been produced at any one or at all grounding points. As this place emitted some explosive gas and as the machine had just completed undercutting the coal, raising a cloud of coal dust, the atmosphere of the place must have been in prime condition to propagate an explosion from the flame which the machine emitted.

"Therefore, we are unanimously of the opinion that due to improper and inefficient assembling of the machine, an arc was formed which caused an explosion in an atmosphere charged with dust and explosive gas.

"For the future safety of the employees and for the protection of this property, we recommend: that the mine hereafter be worked exclusively with approved safety lamps, that all mining machines used for undercutting the coal be of the improved closed type, approved by the U. S. Bureau of Mines, that no open-type motors be used except in places ventilated by inlet air currents, that no switches, circuit-breakers or fuses be of the open type, but be enclosed in explosion-proof casings or break under oil, as required in paragraph 65, Sec. 4 of Art. 11 of the mining law, and that no trolley wires be extended beyond inlet air currents.

"We also advise that all shots be fired by qualified shotfirers, using only permissible explosives, and portable shotfiring machines enclosed in tightly constructed cases. All holes charged for blasting should be tamped with clay or other incombustible material the full length of the hole and all airways should be driven in the same direction as the entries and maintained parallel at the working faces so as to eliminate the excessive use of canvas for ventilating purposes."

Surface Works at Shanktown Mine

Note the fan house on the hill. The fan housing leaked a little after the explosion but was easily put into working order. Probably coal dust played only a minor rôle in the explosion, the mine producing a large quantity of water.

Joseph Struthers, Secretary of Engineers Club, Dies

Joseph Struthers, mining and metallurgical engineer, former secretary of the American Institute of Mining & Metallurgical Engineers and secretary at the time of his death of the Engineers Club, died of pneumonia, at 10 a.m., Monday, Feb. 18.

Mr. Struthers was born in New York, his father being of Scotch origin and his mother of English. He was educated at the College of the City of New York, 1880-81, and graduated as Bachelor of Philosophy at Columbia University, becoming Doctor of Philosophy in 1895. He joined the staff of instructors of the departments of mineralogy and metallurgy at Columbia in 1885 and continued in that work till 1900. He became assistant editor and later editor of *Mineral Industry*, producing, or aiding in the production of, Vols. 8-11. He was field assistant, U. S. Geological Survey, in 1903 and special agent of the U. S. Census Bureau, in charge of reports on the mineral industry of the United States, in 1904. That year he became assistant editor of the American Institute of Mining & Metallurgical Engineers and finally secretary, during which time trips were made by that institute to the Panama Canal (1910) and Japan (1911). In 1904 he was secretary of the Division of Mining at the St. Louis Exposition. Since 1909 he had been secretary and treasurer of the Engineers' Club.

Senate to Approve Probe of Alaska Coal Leases?

The Senate is expected to approve the proposal that an investigation be made of the transfer by the Navy to the Interior Department of leasing unit No. 12, in the Matanuska coal field. This unit was set aside as a reserve by President Wilson, in 1920, following a visit to Alaska of Josephus Daniels, then Secretary of the Navy, and John Barton Payne, then Secretary of the Interior. After the two secretaries had given first-hand consideration to the prospects of naval coal development in the Matanuska field, the departments entered into an agreement to conduct extensive exploratory work to determine the value of that coal deposit as a reserve for naval use.

John E. Ballaine, an Alaskan constructor, in a letter to President Coolidge and members of the Senate insists that former Secretary of the Interior Fall and Secretary of the Navy Denby entered into negotiations for the transfer and lease of the rich naval coal reserves of Alaska to promoters.

Mr. Ballaine charges that big interests are at work trying to hinder the development of Alaska. He declared the coal lease was not effected, but the Navy Department, through the efforts of Rear Admiral J. K. Robison, had refused since to permit use of Alaskan coal by the navy. He added that proposals for the coal leases were like those used later in the Teapot Dome oil transactions.

The quality of the coal has been

F. W. Gray

Recently appointed assistant to the president of the British Empire Steel Corporation, which has many coal mines in Nova Scotia. Always a protagonist for Canadian coal, Mr. Gray recently read a paper on that subject before the Canadian Institute of Mining and Metallurgy, receiving the W. R. Wilson award for that contribution.

conceded for many years to measure up to Navy standards, but underground development revealed that the formation is faulted badly and that the coal seams are crushed to such an extent that the engineers who followed the work are convinced that it would not be possible to mine the Matanuska coal at a cost which would make it possible to compete with the high-grade coals of southern West Virginia.

The actual transfer of the Matanuska reserve was made on May 1, 1922. A study of the property was made by the Bureau of Mines and it finally was decided to close the mine. Before this was done it had been ascertained that no coal operator, who could show the necessary financial backing, was willing to undertake the operation of the mine. Coal deposits in Alaska can be operated only under the leasing system. Several properties now are being operated under such a plan by Alaskan capital. The output of Alaskan coal in 1923 was 40 per cent greater than in 1922.

Brydon Names Committee to Arrange for Convention

John C. Brydon, president of the National Coal Association, has selected the following committee to arrange for the next annual meeting of the association: W. E. E. Koepler (chairman), Pocahontas Operators' Association, Bluefield, W. Va.; C. E. Bockus, Clinchfield Coal Corporation; W. H. Cunningham, Cunningham, Miller & Enslow; W. L. A. Johnson, Southwestern Interstate Coal Operators' Association; F. S. Love, Union Collieries Co.; P. H. Penna, Indiana Bituminous Coal Operators' Association; W. J. Sampson, Witch Hazel Coal Co. After the place has been selected for the convention, two other members will be added to the committee.

Hoover to Continue Reports On Business Conditions

Reports on business conditions and industrial production published by the Department of Commerce will continue to be issued, an official statement issued Feb. 16 said, although Attorney General Daugherty in a recent letter to Secretary Hoover indicated that trade associations might be sharply restricted in gathering statistics which enter into the reports. The Attorney General held that the furnishing of such data to the government probably was lawful, but that dissemination of it by trade associations themselves to members probably was unlawful.

"The Department of Commerce will continue to publish its monthly survey of current business," the statement said. "The information which associations furnish will be used within the limits of department appropriations and facilities in the publications to the extent that it proves suitable.

"The department does not express any views as to the legal status of any association from which it receives the information or any approval of its activities."

Electrical Engineers Discuss Automatic Mine Equipment

Electrical engineers of the northern anthracite region were the guests of the Scranton Electric Construction Co., of Scranton, Pa., at the Engineers' Club, Feb. 8. After the dinner Chester Lichtenberg, switchboard engineer with the General Electric Co., gave an illustrated lecture on the automatic substation. In the course of his talk Mr. Lichtenberg showed the evolution and development of the automatic substation for converting alternating-current electrical energy to direct-current energy for use in and about the coal mines, and also showed illustrations of automatic alternating-current switching stations.

After the lecture E. B. Wagner, electrical engineer of the Lehigh Valley Coal Co., spoke about the success of the Drifton automatic substation, the first installation of this kind made in the mining field. This substation is one of three now operated by his company. In an appeal to the manufacturers to give greater consideration to the adverse conditions under which mine electrical equipment must operate Mr. Wagner gave some interesting figures showing that there is a potential market for about 1,500 locomotives in the anthracite region alone. It was estimated that 15 per cent of these would be of the storage-battery type. The generator capacity required would be about 108,000 kw., most of which probably will be furnished through 600 automatic substation equipments.

Discussion on the question of the motor-generator set versus the rotary converter for mine service brought out the fact that one large manufacturer found that in 1920 rotary converters for haulage service exceeded motor-generator sets in the ratio of 60 to 40; in 1923 the motor-generator set was predominant, the percentages being reversed.

High-Cost Operators Panicky at Likelihood Of Long-Time Wage Agreement

Intelligent Observers See Salvation of the Industry in Long Period of Uninterrupted Competition, Which Would Weed Out Superfluous Mines and Workers

BY PAUL WOOTON
Washington Correspondent of *Coal Age*

Operators of high-cost mines in the union fields are in a state of panic in the face of the probability of the negotiation of a long-time wage agreement, which carries with it the certainty of a long period of uninterrupted competition. Not all of them have learned that there is no salvation in a temporary shortage such as is created by a strike. It may be said, however, that it is only an inconsequential proportion of operators who are so shortsighted as to hope for a strike. An overwhelming majority of operators concede that surplus capacity and the surplus of men must be reduced drastically. Most of them agree with Secretary Hoover that the best way to bring this about is by the continuation of production without interruption.

While figures are not available to indicate the losses which are accruing because of the unproductive capital tied up in surplus mines and equipment, the extent to which the public is supporting coal miners can be grasped by a glance at the following figures:

	Men Employed	Output, Tons
1890	192,402	111,302,000
1900	304,375	212,316,000
1910	555,533	417,111,000
1918	615,305	579,386,000
1919	621,998	465,860,000
1920	639,547	568,667,000
1921	663,754	415,922,000
1922	687,958	422,268,000

This enormous increase in the number of workers which the industry is supporting can be accounted for only by the fact that the wage scales attract too many men into the industry. It is natural that the worker prefers to labor two days per week and earn \$1,500 per year than to receive the same annual income for six days' work per week. In considering the increased number of men in the industry, sight must not be lost of the fact that production by machine has been increasing constantly with a resultant higher output per man.

With the promise of a long period of peace in the industry it would seem that the principal fruits of such a situation would go to the non-union fields. On the face of things, the entire market would seem to be theirs, up to the point of freight-rate limitation. The remarkable success which is attending the mechanization of non-union mines has a serious portent for the union fields. The difference in wage scales even now is great. At some mines, at least, the minimum pay has gone as low as \$3. Drivers and other semi-skilled men are being paid \$3.50. There are non-union mines, it is understood, in which \$4 is the top wage. Cutters are getting 4c. a ton and loaders, in some instance, are getting 32c. a ton.

In the face of such costs, it would seem that the non-union fields could capture most of the market worth

having. To an increasing extent, however, the advantage enjoyed by the non-union producers is being met by unofficial understandings at individual mines between management and men whereby wage reductions are accepted to keep the property in operation. The practice is known to be spreading and some are of the opinion that the union will close its eyes to it so as to allow the employment of the maximum possible number of union men and because by this practice non-union wages will be forced to a level where a fertile field will be created for the seeds of union propaganda.

Mr. Lewis' recent emphasis of the fact that no questionable methods are to be employed by union missionaries is not taken to mean that there is any less determination to extend union territory. It simply means that the policy now in force is much more likely to be effective. The missionary work no longer is being done by the rough-neck element in the union. There is reason to believe that carefully picked union emissaries are now strategically placed in the ranks of the workers in most of the non-union operations. These men will not resort to intimidation. They were chosen because of their intelligence, their plausibility and, their ability to gain the confidence and respect of their fellow workers. While it seems probable that a long period will pass without a strike, a battle royal, nevertheless, impends. Instead of being between employer and employee it will be between union and non-union interests.

Last of the Coal Mohicans

Last of the coal mines to be unionized in Illinois, the old Brush mine, at Carterville, about which such a struggle waged from 1898 to 1905, has passed into history. The tippie is all that remains intact. Removable steel from inside the mine has been taken out and soon the scene of Illinois' longest labor war will revert to prairie land. Troops were sent to Carterville when the struggle was at its height. Miners and strikers fought in bitter warfare, standing in the open without protection. They fired with a wild aim and wasted tons of ammunition, but all warriors came off without a scratch, as they aimed to miss. Houses around the mine still bear the marks of the bullets. Samuel T. Brush, the owner of the mine, finally gave up the struggle of fighting the union and sold the mine to the Madison Coal Corporation, which at once unionized the mine.

Urges Better Ventilation in Anthracite Mines

The Lehigh Coal & Navigation Co. has been requested by the State Department of Mines of Pennsylvania to remedy alleged dangerous conditions in the three collieries operated by it in Carbon County. A report just submitted to the department by three anthracite inspectors, appointed by Secretary of Mines Joseph J. Walsh, copies of which have been sent to Samuel D. Warriner, president of the company, and Thomas Kennedy, president of District No. 7, United Mine Workers, shows that ventilation conditions in the collieries were inadequate when the investigation was made and that there was not sufficient fresh air to dilute the dangerous underground gases. The inspectors reported that they observed "extreme laxity" in the use of safety lamps in the mines, many of the miners going into the shafts without being equipped with the locked safety lamps as required.

The inspectors, Frank Kettle, J. J. Strickler and Edwin C. Curtis, reported that they had inspected the Nesquehoning, the Greenwood and the Lansford mines and said that in each of these mines "the volume of air circulating along the faces of some of the chambers was not sufficient to dilute, render harmless and sweep away smoke or noxious gases as required by Sec. 4, Art. 10 of the act of June 2, 1891."

VENTILATION INADEQUATE

Continuing, the report stated that the system in use to ventilate the faces of certain gangways and chutes was "not good practice." The ventilating fans located on the surface of the mines, the inspectors reported, did not produce "sufficient pressure to force through the mines a volume of air sufficient to remove the danger from gases."

"Practically all of the runways and crosscuts through which we traveled," the report continued, "were too small to permit an adequate supply of air at the pressure produced by the ventilating equipment."

"We cannot impress too strongly upon the officials the positive necessity of seeing that every workman employed in the gaseous mine be equipped with a safety lamp for testing purposes," the report emphasized. "We also desire to call attention to an extremely dangerous practice indulged in by some of the miners, namely, that of hanging their safety lamps on props or timber long distances from their working faces and permitting them to remain there during the day. Those careless persons should be brought to realize that they have an obligation to meet in the way of protecting themselves and others employed in the mine."

"We also suggest that the man in charge of the station at the entrance to a locked safety-lamp section be empowered to prevent any person from passing his station until he has in his possession a locked safety lamp."

The inspectors appended to their report a statement that certain construction work was already in progress at some of the mines designed to improve the ventilation in the mines.

Calls Coal Commission Report On Wholesalers Unfair

The report of the U. S. Coal Commission on the business of the wholesale coal dealers, "through the method by which its conclusions are arrived at and through the language stated in announcing its conclusions, appears to be intent upon creating prejudice on the part of the public against the wholesale coal dealers," according to an analysis made by Edward E. Gore, business analyst, for the American Wholesale Coal Association. "The statements presented," the report concludes, "carry an unfair inference and the conclusions announced are not such as would be reached by those who are familiar with the manner in which business is transacted."

The report states:

"The periods selected for investigation and comment, being the month of November, 1922, as compared with the month of November, 1921, and the week ending Nov. 25, 1922, were a most unfortunate election if the Coal Commission intended to approach the subject in a spirit of fairness, since the periods referred to marked the most violent fluctuations in the prices of coal and the existence of the greatest panic among consumers of coal ever known in the history of the trade.

"Comment is made upon the fact that during the week ending Nov. 25, 1922, the fluctuation in prices resulted to the dealers in differences ranging from a loss of \$2.25 per ton to a gain of \$3.90 per ton on sales of bituminous coal, while the variations in the prices of anthracite during the same period amounted to as much as \$4.53 per ton.

"No better evidence could possibly be produced that the period selected was one of a panic in the coal market and manifestly not a period to be used as a basis for statements intended to inform the public of conditions in the coal trade.

"These violent fluctuations in price should, however, have the effect of convincing the general public that there is in existence between the wholesale dealers in coal no such arrangements as would result in stifling competition. On the contrary, evidence of the most active competition is complete.

"The U. S. Coal Commission seeks to limit the earnings of wholesale coal dealers to a fixed rate of return on their invested capital, wholly ignoring the fact that invested capital is a secondary consideration—the success of a wholesale coal dealer being predicated not upon the amount of capital that he controls but upon the amount of coal that he can sell."

Continuing, Mr. Gore says: "The Coal Commission intimates that an increase in the number of wholesale coal dealers must result in higher prices because of competition on their part in obtaining tonnage to sell.

"The Commission's attitude with respect to this matter is in direct contravention of the general understanding that there are in the United States facilities for the production of nearly double the amount of coal that the country can consume and it is well established that competition among coal producers is as keen, or keener, than

Erskine Ramsay

Mining engineer, coal operator and capitalist, who has presented the first \$100,000 for the construction of an Engineering Hall at the Alabama Polytechnic Institute, Auburn, Ala.

in any other line of like importance.

"The U. S. Coal Commission, while showing the average percentage of gross profit derived from the sale of coal by wholesale coal dealers, fails to make any comparison between the rate of gross profit in the coal trade with the rate of profit derived from the sale of other commodities by jobbers or wholesalers.

"There are few staple commodities and none of any other kind that are sold by wholesale dealers at a lower margin than that taken by wholesale coal dealers. This the public should understand before judgment of an unfavorable kind shall be formed with respect to the dealers in coal."

Washington State Mines Yield Three Million Tons in 1923

Fifty-seven operators in Cowlitz, King, Kittitas, Lewis, Pierce, Thurston and Whatcom counties, Washington, produced 2,946,007 tons of coal in 1923, according to William P. Reese, chief state mine inspector. Of this, 19,937 tons was from a sludge washery of the Renton Coal Co. The largest producer was the Northwestern Improvement Co., which has six mines comprising four district operations. Its output was 1,119,102 tons. The next largest producing company was the Pacific Coast Coal Co., with an output of 618,024 tons. The output per man varied from 0.30 ton per day in one of the smaller mines to 5.07 tons in one of the mines of the Roslyn-Cascade Coal Co. The average production was 3.18 tons per man-shift.

COAL PRODUCED IN WASHINGTON IN 1923

County	Coal Shipped	Total Output	Tons per Man
Cowlitz.....	114	2.37
King.....	634,679	663,061	2.65
Kittitas.....	1,295,030	1,358,359	3.87
Lewis.....	95,544	113,114	3.42
Pierce.....	281,715	355,715	1.79
Thurston.....	256,582	268,202	6.06
Whatcom.....	172,680	187,442	3.83
	2,736,232	2,946,007	3.18

Missouri Retailers Charged With Unfair Methods

The Missouri State Retail Coal Merchants' Association is charged with unfair methods of competition in a complaint issued last week by the Federal Trade Commission. The organization, which is also known as the Mid-West Retail Coal Association, is composed of retail dealers in coal in Missouri, Arkansas and Illinois.

J. B. Sanborn & Co., of Chicago, Ill., a coal-trade directory publisher, and the following officers and directors of the coal association also are named as respondents in the case: R. D. Kelly, W. A. Storrs, H. R. Oglesby, P. L. Rupp, F. W. Schramm, F. A. Parker, F. W. Autenrieth, E. J. Wallace, Arthur M. Hull, S. P. Guthrie, W. R. Creasey, J. B. Hallquist, V. C. Elmore, W. F. Sprague, G. V. Montague, Frank Wilmes, H. F. Shrankler, William Farrell and J. E. Cowling.

According to the commission's complaint, the respondents co-operated in preventing the distribution of coal in the territory served by the association's members, except through the so-called "regular" channels and prevented "irregular" dealers, co-operative purchasing associations and other consumers from obtaining coal at wholesale prices, or from any other source than the so-called "regular" dealers.

Indiana Feels a Pick-Up

The opening recently of the Ventura mine, formerly the Riverside mine, by the Coal Bluff Mining Co., Terre Haute, and of Miami No. 10 mine is indicative of the general increase in activity felt by the industry in the western Indiana district. Twenty-one mines are now operating near Clinton and many mines that had been idle for long periods of time are now working steadily.

The Ventura mine, which had been idle for some, has been remade into practically a new mine. A steel tippie has been erected with the latest type of picking tables and loading booms for the sizing and preparation of the coal. The tippie is built to handle four tracks.

Some time ago the opening of the Dixie Vein mine, the Miami mines 6, 8 and 10, and the Oak Hill mine gave impetus to the business and furnished employment for hundreds of miners.

Statistics from the Indiana Coal Trade Bureau compiled for the week ending Jan. 26 show that the mines in operation worked over 51 per cent of the time. One hundred and seventy-seven mines reported in operation to the bureau, although many Indiana mines are not included in that number.

Causes for the sudden spurt in the coal-mining business are said to be the "getting ready for April 1" policy. Some of the railroads are storing coal and many manufacturers fear a coal miners' strike, it is said.

William L. Allen Dead

William L. Allen, of Scranton, well-known coal operator, died Feb. 18. He was president of the Scranton Coal Co., the Price-Pancoast Coal Co. and the West End Coal Co.

Practical Pointers For Electrical And Mechanical Men

Some Reasons Why Chemical Specifications Of Cast Iron Are Undesirable

IN RECENT years, as the consumer of iron castings is becoming familiar with the methods of foundry operation, there has come a marked tendency to include chemical requirements in the specifications for cast-iron products, evidently because of the success of such a procedure in the case of steel. The movement has gone so far that the new tentative specifications for chilled iron car wheels, as first reported, actually demanded the given analysis in full.

Cast iron, in contradistinction to steel, is an extremely non-homogeneous material, highly useful for its fine resistance to compression, ease in machining, cheapness and adaptability to simple melting and molding processes. Yet, while steel may be perfectly homogeneous throughout the piece, the surface and interior of a casting are widely different in their physical properties, as brought about by carbon condition changes due to the rate of heat abstraction during setting. Further, the subsequent heat treatment to which steel is amenable finds almost no counterpart in cast iron.

On the other hand, while it will be shown in what follows that the full chemical composition when specified in purchasing iron castings serves no useful purpose, it is eminently proper, and on occasion extremely important, that one or more injurious elements always present in cast iron be limited to given maxima. The experience of the foundryman and the consumers of his product would go for naught if this limitation could not be made part of the specifications governing their transactions.

The first reason why the introduction of chemical requirements into the usual specifications for iron castings is undesirable is that wherever this has been tried in a general way it has failed of its purpose. One prominent engineering society, which went into the subject very thoroughly, found that to include all the compositions of castings coming under each separate line of work for which special specifications were to be prepared would mean that the limits for the several elements in cast iron would have to be held so wide that no useful purpose would be served. The project was therefore abandoned.

Another engineering society, through its specification committee and in conjunction with a similar committee of the foundrymen interested, has just come to the same conclusion, after studying an elaborate series of tests

for which chemical data were available to check up with the physical results. They would not fit, though showing general parallel tendencies. Perhaps the reason for this in part lies in the variations in practice at the several foundries. Procedure in founding iron is cruder and hence more widely fluctuating than in the finer and more exact process of steel making.

The second reason why chemical compositions at given figures should not be required of foundrymen in specifications they are to work under is that the history of the development in foundry practice has shown that present-day compositions of castings are considerably different from what was considered necessary some years back. Silicon is a good instance of this.

With more knowledge on the bad effects of dissolved iron oxide in cast iron, and definite information on the progression of cupola melting, the same grades of soft iron castings are now produced with much lower silicons than formerly. Much of the trouble formerly attributed to sulphur is now known to have been caused by oxidation phenomena. Even phosphorus has come in for greater attention than formerly, though in the direction of limiting it more closely, for with the better irons that can now be made, the phenomena of segregation have become more acute, as the metal remains fluid longer.

The general use of steel scrap in cupola mixtures, for cutting down the total carbon and thus strengthening the iron, has upset many notions on compositions as going with physical properties, and with this new variable introduced into the problem, already complicated with many others, it is very nearly hopeless to formulate a series of constants such as could be used to build up a set of compositions that could be called standard.

None the less, the purchaser of castings, in the course of his experience with the product of the foundries he deals with, may develop a line of compositions which will give good results, and naturally he will want to apply this information for his own benefit. There is no reason why such compositions should not be given in the specifications issued as "recommended practice," but not as essential requirements. The foundryman who works under such specifications will do his best to comply with them and get the physical prop-

erties demanded. But should he find himself unable to do this, he will be free to use his own experience in getting the physical properties required by using compositions of his own, without having his product rejected.

The cases where maxima for certain elements may be specified are somewhat different. Where it is known definitely that when a given maximum percentage of an element is exceeded failure may result, it is the part of wisdom to apply this limit. The case of sulphur in cast-iron water pipe is an example. High sulphur here may cause breaking when the shock of water-hammer is applied. It is perfectly justifiable, therefore, to state in the specifications that sulphur shall not exceed a given percentage. Phosphorus, similarly, is known to give serious segregation troubles when sections exceed 2 to 3 in. in thickness. Hence a limit is proper where the work will exceed these sections.

The conclusion derived from the above discussion is that it is unwise to add to the troubles of the foundryman by imposing chemical requirements upon him in addition to physical ones. Either one or the other should be imposed, but not both. If the consumer wants a given composition, the foundryman furnishes it, but then the consumer is responsible for the physical characteristics of the work. But if the consumer wants the castings for his service requirements, the foundryman should be unhindered in working out the problem, so long as the service requirement tests are met.

RICHARD MOLDENKE.

Allowing for Expansion and Contraction of Copper

For the same temperature a piece of copper will expand more than a similar piece of iron or steel. Further, it is usually found that in a motor, the copper becomes hotter than the other materials of which the motor is made. Therefore, it is necessary to provide means for the copper to expand and contract to take care of the relative motion between the different materials for the changes in temperature. A common error in this respect is to anchor the wiring around frame connections to the frame proper when it should have been securely bound to the windings, so that it would be free to move with the windings. It is obvious that this is more important with solid-strap conductors than with flexible cables.

Replacing Broken Gear Teeth

The building up of cast-iron gears offers possibility for wide use of the acetylene torch—for instance, in replacing a drum gear on a room hoist.

Fig. 1—Building Up Metal for New Gear Tooth

Here the operator fills in the section of the gear where a tooth has been broken.

By placing a strip of $\frac{1}{4}$ -in. steel plate on either side of a gear section where teeth are broken off and clamping these with a $\frac{3}{4}$ -in. round of soft iron, bent to a U so as to press the plates against the sides of the gear, a pocket may be formed. This pocket then should be built up with cast-iron welding rods by means of an acetylene torch. The gear is then placed on a boring mill and the built-up section faced off. Then it is placed in a shaper and teeth are cut from the solid metal.

The machine work is laid out as follows: The side of the built-up section is chalked, a templet is placed over the chalked area and the teeth marked out. A round-nosed tool is prepared by grinding to cut the exact tooth shape with only a downward feed of the

shaper, the templet aiding in obtaining the correct shape of each tooth to be cut. The templet is cut in the rough from a piece of thin sheet iron and then filed to shape by clamping the sheet iron against a new gear which is a counterpart of the one to be repaired.

This job is a great money saver when many gears of the same size and shape are repaired. It also is economical to go through the entire process described for only one gear. The cost of making three new teeth, including materials and labor, is about \$1. Steel gears may be repaired in a similar manner, of course, using steel instead of cast-iron welding rods.

Grindstone for Sharpening Axes, Hatchets and Picks

One or two old-fashioned grindstones, depending upon the size of the plant, are as important a part of the equipment in a mine shop as they are a necessity on a farm. From the point of safety they are highly desirable, as they can be used by inexperienced men for many sharpening jobs which too

Mine-Shop Grindstones

Slow-moving stones like these may be used with relative safety by any workman around the mines.

commonly are done on the high-speed emery wheel.

Approximately, for every 1,000 tons of coal mined, 100 loaders are employed, each of whom should be provided with a sharp ax, because it is needed for efficient work in placing safety props in the chambers and along the mine roads. Members of timber crews also must have these implements; mine electricians and brattice men cannot work without good one-hand axes, nor can a carpenter do much without a sharp hatchet. A slow motor-driven grindstone of fine sandstone will give a keen edge to all these tools. And loaders can grind their own picks on them too.

At the Lynch Mines of the U. S. Coal & Coke Co. coal loaders and others fought for the use of emery wheels to sharpen their tools. The practice was both dangerous and bothersome, so the company installed two grindstones. On them, as the illustration shows, four men can work at one time. All danger

of injury is removed and interference with shop operations is eliminated.

Ignorant practices in the use of an emery wheel might cause it to burst or the tool being sharpened might be thrust back because of the great speed of the wheel, and thus a man might be severely injured by it. Worst of all, flying particles of emery are likely to cause blindness if the eyes are not properly protected with goggles. At best it is a difficult undertaking to teach these men to use goggles or to keep a supply of such glasses at the emery wheels when they are used promiscuously.

Nicking of Copper

The nicking of copper is an abusive practice to be avoided. It is very easy to nick copper with the sharp edge of a metal drift or other tools such as are used in connection with the winding of armatures. It is preferable to use a hard-fiber drift and drive leads down into commutator neck slots by using a copper filling piece placed on the lead to receive the blow from the hammer. Another source of trouble due to nicking of copper is found in field-coil cable leads breaking at the point where the insulation has been cut off with a knife, the break having been started by the knife nicking the strands of the cable. Such nicks are the starting point of breaks, as surely as are those which the glazier cuts in glass when he is cutting it for the window pane. Extreme care should be used in removing insulation on all cables and wires of small cross-sections.

Problems In Underground Management

Shall We Protect Mines from Gob Fires by Stowing, Ventilation or Stoppings?

Most Gob Fires Occur in Thick Coal Because in That Case Many Pillars Are Left—Mine in Edmonton, Alta., Being Worked by Tunnels Cut in Solid Rock with Small Panels

DISCUSSING, in the *Monthly Bulletin* of the Canadian Institute of Mining and Metallurgical Engineers, the avoidance of gob fires in coal mines, J. B. De Hart, mining engineer, Cadomin Coal Co., Cadomin, Alta., a company that has experienced two of these fires, says that of the six fires mentioned by J. A. H. Church in a recent article, five are in thick pitching beds. These fires occurred in the following mines during the years shown: At Frank, in 1910; at Lovett, in 1916; at Cadomin, in 1920; at Yellowhead, in 1922, and at Cadomin, in 1923.

Every one of these occurred, as Mr. Church pointed out, in a seam having a thickness exceeding 12 ft.; none of them has been extinguished though in every case large sums of money have been expended and considerable risks taken in fire fighting.

SEALING AND VENTILATION CURES

Mr. De Hart says that spontaneous combustion undoubtedly arises from the oxygenation of the coal faces, with the consequent heating of the coal. If the air is excluded oxygenation is prevented; if a ventilating current is provided the heat is removed as generated. Consequently fires will be avoided if air is excluded from gob or if the gob is so well ventilated that any heat generated will be removed by the current.

He continues that in his belief thick seams do not heat because they are thick but because, being thick, the extraction is imperfect and much coal is left to become oxygenated. Thinness of seam offers no special immunity. If imperfectly mined it still would be subject to gob fires. Stowing would enable the coal to be completely removed, but, unfortunately, due to the lack of material for such stowing, the cost of filling the working with sand or other fine material would be prohibitive. However, broken rock could be fed in by chutes. With present methods only about 50 per cent of the coal is recovered, and, taking into account barrier pillars and fire losses, perhaps not more than 40 per cent.

Ventilation of the gobs, he says, would require an uncertain quantity of air at a water gage not determinable except by experiment. He is disposed

to think the cost would not be prohibitive; in any event much less expensive than a fire.

SURFACE CAVES FURNISH AIR

Coal piles sometimes will heat dangerously in six weeks from the time the coal pile is formed. Consequently heating of coal always is imminent. When drawing pillars, the roof caves, driving air to the surface if the fan is forcing air into the mine or drawing air from the surface if the fan is exhausting. Consequently the gob receives air and may heat before all the pillars are drawn. Earth might be hydraulicked with a monitor into the caves, but this could be done in the coal fields of Alberta only during the warm months.

If heating did not occur till the pillars were drawn the gob could be sealed off in the mine. If, however, the gob had heated, a current would be established between the surface and the gob, the heat furnishing the means by which the gob would be ventilated sufficiently to permit of further heating, but in insufficient volume to cool off the heated area.

It would seem well, says Mr. De Hart, to leave the pillars near the crop and to seal openings leading to the surface so that the ground will not cave to the surface, at least not till the pillars have been withdrawn and the place has been sealed. Along the crop, pillars should be left for a sufficient depth from the surface to prevent caves. Probably 75 ft. would suffice, much of which would be wash and worthless coal. With this provision the air circulation would be kept from the gob and concentrated at the working faces. The gob might then fill with methane, as in the Reaver method of North Staffordshire, when the gob is kept free of fire by drowning it with an accumulation of firedamp. The mine should be ventilated by an exhaust fan so that the gas in the interstices of the gob would be put under increased pressure should the fan stop. This method, Mr. De Hart thinks, would be safer than running the risk of a mine fire.

He advocates also drawing pillars up the pitch, thus making it possible to put

stoppings at the lower end of the room. This would give better extraction and less ventilation of the coal faces. Working downward, triangular pieces of coal are left projecting into the gob. These corners naturally squeeze and form dust, ideal starting points for fires.

Another method he considers is using small panels—so small that they can be completely worked out and sealed before a fire appears—but, he concludes, this would give a panel life too short for economical methods of working with a large output. As the pillars would be drawn in a confined area the percentage of extraction would be low and more coal would be left in the gob. The retreating method would, of course, be the ideal system, but it is too expensive to be considered.

Experiments are being made southwest of Edmonton in developing a mine by means of rock tunnels. This is good practice because it cuts the cost of upkeep of the main haulage road and gives some assurance that if, in spite of all precautions, a fire should occur, it can be sealed off in the rock and the seam opened beyond the fired area. Further, the size of the panels is being limited so as to supply about one and one-half or two years' coal.

Short Fuses Are Suicidal

BY W. J. GERMAN
Technical Representative
E. I. du Pont de Nemours & Co.

Few mine officials know how a miner uses short fuse. When he is ready to charge his shothole he cuts 7 in. or less of fuse, attaches a blasting cap to it and places the cap in the cartridge of dynamite, probably lacing the fuse through the cartridge as shown in Fig. 1.

If he intends to use three sticks for

Fig. 1—Badly Laced and Too Short to Reach Mouth of Hole

Fuse is laced through cartridge and is so short that it must be lit before the cartridge is inserted and before the tamping is wedged behind it.

the charge, he places two sticks at the back of the hole, then puts the primer stick in the mouth of the bore and lights the fuse. Next he rams the primer as far as it will go in the hole, puts in a 6- or 8-in. dummy of tamping material and tamps it reasonably tight. He then makes—or tries to make—his escape to the nearest cross-cut.

Frequently as the dummy is rammed back into the hole it curls up the fuse and this causes a misfire or delayed

Fig. 2—Cartridge Properly Primed

The fuse is pushed into the side of the cartridge in a hole made for that purpose. It is then tied in place. The fuse is cut off so long that it will reach to the mouth of the bore hole.

shot. Then there are times when the miner gets in a hurry and fails to clean out the holes, in which case the charge with the lighted fuse gets hung up a part of the way back in the hole. He misjudges the time it will take for the fuse to burn, and through his efforts to force the charge back he stays too long and is injured by the shot.

The use of short fuse has been responsible for many serious accidents and it necessitates loading about a third more explosive than really is necessary to bring down the coal satisfactorily. In some states the use of short fuse is against the law, and it is contrary to good practice and common sense everywhere.

Safety in Extracting Coal and Salvaging Timber

Some people maintain that in mining coal the posts should be sacrificed and no risk should be taken to salvage them. In some mines, however, the reclaiming of timber is considered important not alone for the value of the timber but to control the fall of the roof.

Wherever timber is reclaimed the

Draw Pillars Right and Save Timber

The stages in withdrawal of timber. Fig. 1 shows the crosscut completed so as to provide a small pillar adjacent to the goaf. Fig. 2 exhibits the small pillar still further reduced at the far end. Fig. 3 shows the small stub pillar which protects the man who pulls the timber. This is finally shot out and lost.

work should be supervised intelligently and with care. If the miner were allowed to use his own judgment he probably would adopt such a dangerous system of robbing pillars that he at any time might be obliged to run out of the place, occasionally losing his tools and the mine car also. Under proper directions he might obtain the same quantity of coal at less risk and yet save practically all the timber.

A safe way in which this may be done is to drive a crosscut through the rib near its end and then remove the small pillar thus formed, starting near the gob and leaving nothing but a small stump near the main roadway of the room.

After removing the track in what was the crosscut take an axe and chip one of the remoter props at one side immediately under the cap piece, so that with a long chain and post puller the post can be pulled with safety. Continue this process until the forty or fifty posts are all out. Then a hole drilled into the stump which was left

standing should be filled with a small charge of powder and shot by an electric shotfiring battery. By this method it is possible to save all the posts and yet obtain 95 per cent or more of the coal. Thus the posts will be removed without destroying one of them and without a waste of powder.

ROBERT W. LIGHTBURN.

Gans, Pa.

Why Did the Shots Explode Prematurely?

Recently we have had some peculiar accidents in the firing of shots when coal was being blasted. We are anxious to obtain suggestions as to the cause of these dangers. We use only permissible explosives for blasting the coal and No. 6 caps and fuse for igniting the shots.

On two separate occasions the miner had tamped his dummies on the charge, lit the fuse and retired to safety when an explosion followed that sounded as if only the cap had fired and not the cartridges. On returning to the face, however, it was found that the blast had blown out the tamping. The fuse was seen still burning but the cap had not fired; it went off a little later. There is no gas here and we are at a loss to understand just what occurred.

Some years ago I recall that the same thing happened to me when sinking a well, and it seems probable that others have had the same experience at times and may be able to explain the true cause.

J. H. SMITH.

East Lynn, W. Va.

This question being submitted to three of the principal powder companies manufacturing blasting powder for mines, brought the following replies:

"What seems like a premature explosion of a cap can be caused by a tight pinching of the fuse. If a small piece of fuse is held and squeezed as tightly as possible between the jaws of rather broad-mouthed pliers and, while so held, the end of the fuse is lighted, when the fire strikes the compressed part there will be an explosion of considerable force.

"Now, it is conceivable that fuse in a borehole might be so pinched between pieces of rock that a sufficiently strong explosion would blow out some of the tamping. It might blow the fuse with the cap attached out of the hole; but it is difficult to believe that such an explosion would blow the main charge out from the hole, if that is what occurred."

A second letter reads as follows: "This occurrence as described appears to have been caused by an extensive 'side spit' of the fuse, due probably to breaks caused by unrolling it and straightening it out too roughly, the fuse being either cold or somewhat dry from age. In the case mentioned it is possible that the 'side spit' ignited some fine dry 'bug dust' or coal drillings used as tamping and that sufficient gas was formed in this way to blow out the remainder of the tamping and carry the fuse with the detonator attached,

drawing it from the explosive charge.

"If the primer was not the last cartridge loaded, the explosion could have been caused by ignition of explosives from 'side spit' of fuse, this ignition resulting in a partial explosion of the charge from high temperature and pressure.

"It seems most likely, however, that what did occur was the ignition of a small feeder of mine gas by 'side spit' of the fuse. This would have resulted in the slight explosion that the miner asserts that he heard. Such a partial explosion could easily have drawn the burning fuse and detonator from the primer. The similar occurrence, in sinking a well, was in all probability due to ignition or partial explosion of the charge from a 'side spit' of the fuse. It is quite likely that the primer was not the last cartridge loaded in this case. Assuming that dry coal dust was not used for tamping, there could have been no mine gas present and we are then unable to explain the occurrence, either in the shot in the mine or that in the well."

A third letter read as follows: "From the description given of this incident it appears that the fuse probably was laced through the cartridge or in close contact with it and that the burning fuse ignited the explosive at such points. The hole being well tamped, the gases produced by the burning of the fuse and explosive might develop sufficient pressure to blow out the charge with the tamping. This would not produce a loud report, and this would agree with the reported conditions, it being stated that the noise was not as loud as would have been expected from an explosion of the entire charge. The fuse, of course, would continue burning until the fire reached the cap, which would then explode. This is the best and most plausible explanation of such occurrences, which have come to our attention on previous occasions."

In the opinion of *Coal Age*, the most plausible explanation of this occurrence is that one of the explosive cartridges was ripped or torn by a sharp jutting piece of rock or coal in the side of the hole as the cartridge was being pushed home. The injury to the cartridge may have caused a trail of powder to be left from that point to where the injured cartridge finally rested.

Now, assuming that the primer, containing the cap attached to the fuse, was the last cartridge inserted in the hole and the injured cartridge was next below this, it is quite possible, and indeed probable, that the burning fuse ignited the trail of powder and this carried the fire quickly past the primer and ignited the cartridge below it. In that case the resulting explosion would blow out the primer, the tamping and the unburned portion of fuse with the cap attached. The primer itself may or may not have been ignited by the flame of the exploding cartridge, the latter being most probable. Such an explosion would most naturally cause a blownout shot, owing to the full force of the charge being developed slowly.

Discussion

Why Peat Grew Rapidly When Coal Was Formed

With Two per Cent of Carbon Dioxide in Air Tissue Was and Is Rapidly Developed, but for Seed Development Certain Rare Elements Are Needed

FOR some years I have been operating a greenhouse with an atmosphere in which the percentage of carbon dioxide is artificially increased. This has increased the rate of growth of any plant I have used—celery, pansies, etc. Unfortunately, another influence is to make the plants woody, without seed and with warty fruit.

It is well known that in the ages when coal was deposited, approximately 2 per cent of carbon existed in the air, whereas the present atmosphere contains only 0.03 per cent. In the interval since that time a large quantity of this gas was absorbed by the action of plants and certain small organisms, and, as a result, we have limestone, oil and coal deposits, etc. The carbon dioxide that the vegetables of that period absorbed is now locked up in Nature's safe-deposit vaults; an impoverished atmosphere is left for the plant, which assumes a commensurate feebleness.

Biochemically we find that, other things being equal, the percentage of carbon dioxide on the leaves determines the quantity of starch formed and the growth of the plant. In short, double the carbon dioxide in the air and you double the plant's growth. Quadruple it and you quadruple the starch formation. Multiply the percentage of the gas by sixteen and the plant grows sixteen times as fast as in the air of today. It is important that the gas come in contact with the stomata or the breathing cells.

Now, as was stated, it is unfortunate that this growth is uncontrollable and woody, for every power house pours out the equivalent of tons of fresh vegetables and fruit. We have obtained luxuriant rose bushes but without roses, cucumbers that were warty and seedless, celery that could be a caveman's war-club, with, of course, a lot of good fruit accidentally produced in isolated tests.

After years of research I have found out the scientific key to the matter. We have disturbed Nature's balance brutally, tried for production without regard for quality. We must find how to use tact with Dame Nature.

A companion research has developed certain facts and rules as to the effect of rare minerals and elements on the growth of organisms. For instance, I find in all the glands called "ductless" and made notorious by the "monkey-gland" operation certain rare elements

as lithia, zinc, vanadium, molybdenum, nickel, iodine, arsenic, manganese, tin, copper, and so forth, and that these play a dominating biochemical rôle even if present in such small proportions as one-hundredth of a grain in an organic form. For instance, as little as two or three milligrams of nickel, chrome, tungsten and other elements in an organic form in bread will enable the ductless pancreatic gland to make for a diabetic the insulin for sugar oxidation. This has been tested out in several clinical cases. Even trees and other plants have their own endocrine glands. They are merely storehouses for the rare minerals and factories for

working them up into products useful to the organism.

It remains to learn the application of this principle. Referring to "Principles of Biology" by Herbert Spencer, edition of 1898, Vol. 1, pages 272 et seq., we find the fact that there are in life two principles of growth, called by him "gamogenesis" and "agamogenesis." In short, the latter is the tissue-producing force; the former the seed-producing force.

Therefore, when we increase the percentage of carbon dioxide, we increase the tissue-producing force and produce a distortion of nature. Accordingly, we must increase it in proportion with the seed-producing force. Then, the plant gets an arrangement pleasing to its nature and we have speeded up the growth normally.

This can be done in a greenhouse by a soil rich in ordinary manure with which is incorporated certain organic compounds of lithia, manganese, nickel, chromium, tungsten, etc., to give life to the tissue.

The matter is now in shape for small-scale tests and I would be pleased to give any interested experimenter an adequate quantity of the gamogenetic fertilizer.

W. McA. JOHNSON.

Argus, Pa.

Ignition of Gas by Sparks Struck by Falling Rock

Because of my former association with and employment in the Bellevue mine, of the West Canadian Collieries Co., Alberta, Canada, mentioned in the reply to the inquiry regarding the possibility of gas being ignited by sparks struck by falling rocks in mines (*Coal Age*, Nov. 8, p. 711), the remarks of the editor on that subject greatly interested me.

As he has already stated, a series of mysterious explosions took place at that mine, and the cause was generally believed to be the ignition of gas by sparks emitted by falling rocks. When the second of this series of explosions occurred I had been in charge of the mine only nine days.

Unfortunately, the verdict of the jury at the inquest seeking to ascertain the cause of the accident was based on an assumed theory of percussion advanced by James Ashworth, a mining engineer, who was called as an expert. The verdict read as follows: "We do upon oath say that thirty men came to their death by carbon monoxide poisoning and fractured skulls, as the result of a concussion of air caused by a fall of rock in chutes Nos. 76 and 78."

Realizing that the responsibility of reopening and operating the mine devolved upon me as superintendent, and not feeling satisfied that the verdict of the jury was in line with the facts, I proceeded in company with the mine foreman to make a careful and thorough inspection of the mine. The investigation satisfied me that beyond a doubt the explosion had originated in the neighborhood of No. 65 chute.

In that chute we found that a fall had occurred at the surface pillar above the fourth cross-pitch. According to the evidence of two witnesses, gas had been found at this point two days previous to the explosion, and in making my examination of the place I also detected an explosive body of gas.

Later, my conclusion was substantiated by the report made on this explosion by J. T. Stirling, provincial inspector of mines, and Professor John Cadman, of the University of Birmingham, England. In this connection, the detailed account of my investigation, which was published in *Coal Age*, Vol. 3, p. 985, under the title "A Gas Ignition Controversy," will be of interest.

Personally, I am of the opinion that there is much danger of an accumulation of gas being ignited in any mine where the roof is of such a nature as to emit sparks when subjected to the grinding action that occurs immediately before a fall. On certain occasions I have heard the roof rock crack with a sound like the report of a large gun. Bright sparks also are emitted when such rocks strike each other when pieces of the roof fall.

In my opinion, it is of great importance for the management of mines where explosive gas is generated, that samples of the roof rock be subjected to a practical test to determine their ability to emit sparks when weighting or falling. The results of such tests should afford valuable information that would guide the management in the selection of a method of working and a system of ventilation that would reduce this hazard to a minimum.

Welch, W. Va. J. W. POWELL,
Contracting Engineer.

Production And the Market

Gradual Increase in Buying of Soft Coal Noted; Quiet Spot Selling; Contracts Move Steadily

Without any considerable change in the situation that has ruled for several weeks, there has been a gradual but noticeable increase in buying of soft coal. Numerous large consumers have bought quietly of the free coals, while contract holders have taken steadily of their quota. Of course, the topic of conversation in the market has been the Jacksonville conference, and while the outcome is evident consumers hesitate to act for the future until the agreement is signed. Meantime contract making is practically at a standstill. In some quarters predictions are made of a lifeless market if a long-term agreement results.

Some markets are encouraged by the greater activity in steel operations, but these expectations may be offset by curtailments in the textile and other industries.

Coal Age Index as of Feb. 18 is at 186, a decline of two points from the previous week, the average price being \$2.25, also a recession of 2c. from Feb. 11.

Consumers' Eyes on Jacksonville

The accumulation of lump and middle sizes of coal in Illinois and Indiana and the difficulty in selling has caused numerous "no bills." Salesmen are experiencing difficulty in moving eastern Kentucky coals while central Illinois domestic sizes, due to warmer weather, have become sluggish. Cancellations of orders for the larger sizes have caused a cut in production and an upward movement in screenings, and as a result buyers have been looking to other fields for lower-priced coals. Consumers are watching the outcome of the Jacksonville conference.

Retail dealers in St. Louis report a good trade for the middle grades and cheaper coals, with a slow movement for the higher grade coals, but scarcely any activity in smokeless, anthracite or coke. The southern

Illinois field was the scene of more trouble at Herrin, with the mines in the district generally working about four days a week. "No bills" are prominent in the Standard fields with the mines averaging two or three days a week. If car supply was adequate the mines in eastern Kentucky could work six days a week, according to some operators. As it is, supply is cut down to around 55 per cent. There is a good demand for coal as a result of winter weather and reduced stocks. The Northwestern markets are active.

The domestic trade in Ohio is brisk, but the contrary is reported of the steam-coal market. Consumers of steam coals are showing no disposition to increase their stockpiles and buy only for current requirements. Screenings are off because of the larger production of lump, while railroad buying has slowed down due to the favorable outlook at Jacksonville. Numerous local strikes are reported in the Hocking Valley district. Better market conditions are indicated at Pittsburgh. There are a few visible signs of betterment in New England, accompanied by an increase in the number of inquiries for small lots. Along the Atlantic seaboard everything is quiet and uninteresting. Tidewater business is quiet but more activity is reported from the line.

Production of soft coal during the week ended Feb. 9 jumped to 11,531,000 net tons, as compared with 11,337,000 tons the previous week, an increase of 194,000 tons, according to the Geological Survey, while the output of hard coal reached a total of 1,906,000 net tons, an increase of 13,000 tons when compared with the previous week. At present anthracite is being produced in smaller quantities than during the corresponding periods of 1923 and 1921, but is slightly above the figure for 1922.

A fair demand continues from foreign buyers and

(a) Subject to revision. (b) Revised from last report.

while not much actual business is reported the prospects seem good. Inquiries come mostly from France and Italy. The South American market is reported as quiet. Baltimore reports a disappointment in the export situation for the first ten days of February. Dumpings for all accounts at Hampton Roads during the week ended Feb. 14 were 395,464 net tons as compared with 369,171 tons in the previous week, an increase of 26,293 tons.

Middle West Has Too Much Lump

No-bills on the middle sizes and even on big lump are accumulating at most Illinois and Indiana mines and are hard to sell in Chicago and the Midwest markets. Eastern Kentucky lump coming into this region has a hard time moving at \$3.25, the average being close to \$3. Central Illinois domestic sizes are sluggish at the same price and the best southern Illinois runs from \$3.50 to \$3.75 with evidences of softening under a spell of warmer weather. Cancellations have not grown numerous yet, but they are expected.

St. Louis Keeps Busy

Seasonable weather continues and the St. Louis retailer finds his business good on the middle grade and cheaper coals. There is some movement of higher grade coals, such as Franklin County, but nothing to speak of in anthracite, smokeless or coke. Country domestic is fairly good, but calls are for cheaper coal as a rule. Dealers seem to keep a pretty fair supply ahead in their bins. Local wagon-load steam continues good, while carload shows an easing up and the production is greater than the demand. Country carload is easy.

Railroad tonnage shows up fairly good out of southern

Coal Age Index of Spot Prices Bituminous Coal F.O.B. Mines

	1924			1923
	Feb. 18	Feb. 11	Feb. 4	Feb. 19
Index	186	188	187	288
Weighted average price.....	\$2.25	\$2.27	\$2.26	\$3.49

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States weighted first with respect to the proportions each of slack, prepared and run-of mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Illinois the past week, although the movement of cars is slow. Several mines around Herrin, in the Carterville field, have been idle on account of the trouble between the law-enforcement element and the bootlegging element. At the present time there are 1,700 soldiers in the field and this has had some effect on the foreign miners who are refusing to work with the American miners who belong to the law-enforcement organization, which is affiliated with the K. K. K.

The mines in all southern fields are getting from three to four days per week work, which is good and is accounted for by the cold weather. The Mt. Olive district is doing remarkably well, with good demand for domestic, and screenings seem to keep moving. The railroads are taking the egg and nut. In the Standard field there is an overproduction of all sizes and nearly all mines have no-bills, excepting on a cold day when they may clean up. Working time averages only two or three days.

Kentucky Finds Trade Good

It is asserted by the eastern Kentucky trade that a good many mines would be operating six full days a week if the car supply was adequate, but, due to increased general

buying and the fact that a good many cars are on long haul, supply is now down to around 50 or 60 per cent in eastern Kentucky. Practically all large mines are operating. General demand has been good, as utilities, gas and by-product plants, industrial plants and railroads are all needing more coal as a result of a hard winter and the fact that stockpiles are low.

Favored by a steady car supply the western Kentucky operators are managing to get out a good tonnage and there isn't much trouble experienced in getting orders. The South is buying an abnormally large amount of coal this winter, having experienced more bad weather than for years past. Western Kentucky screenings have been advancing, due in part to alleged buying on the part of Chicago brokers for the Commonwealth Edison interests. At any rate screenings, which had been selling at 80@90c., suddenly have advanced to \$1@1.10 to the trade on pea and slack, and \$1.20@1.35 on nut and slack. Prepared sizes show no change. With a range of from \$1 on screenings to \$3 on best block coal, the field could be in much worse shape.

Business at Duluth was good last week, with orders plentiful, and coal men taking the attitude that a large amount of the coal on the docks will be sold by the time navigation opens. The general opinion is that a strike will not occur, but even at that few can see any definite loss, as the way coal is going shows that a large surplus will not have to be held over. It is estimated that 4,200,000 tons remain. Exactly how much of this is free is uncertain, but the major portion is already contracted for. The prices of soft coal are firmer. Screenings as a whole are showing strength. The fall-off in prices reported last week has done much to stimulate trade. The failure of water power in the iron ranges also has taken much coal.

There is a brisk demand at Milwaukee for coal both for local and country delivery. The dock yards are well supplied with all grades of coal, but jobbers of rail coal say prepared Pocahontas and western screenings are a little hard to get at present. One cargo of soft coal which was held afloat was unloaded this week. Prices of coal and coke remain unchanged.

A slight decline was noted in the sales of Colorado coals during the past week. "No market" reports show that 20 per cent of the working time lost was attributed to this cause. Prices remain unchanged and the present supply of labor seems plentiful. The transportation and car-shortage situation has been favorable throughout the state except in Routt County, where more than 85 per cent of the full working time was lost for this reason.

A slight surplus of all grades of coal has begun to accumulate at Kansas mines, which, after six weeks of almost full-time operation, again are cut down to approximately two-thirds time. The present slump marks the end of one of the most profitable periods since the war for the Southwest.

Slight shading of prices again has developed in Kansas City, though it is encountered little throughout the rest of the Southwestern district.

Published quotations remain unchanged. Kansas lump is quoted at \$5; nut at \$4.25; mine-run at \$3.50 and screenings at \$2.25.

The domestic market at Salt Lake City is absorbing the greater part of the output of Utah mines. Consumption has fallen off as a result of the sudden break in the weather. Mines are now working about three days a week. Stocks in Salt Lake City coal yards have increased during the past ten days, due to pressure from operators who desired to keep mines open. The situation in regard to intermediate sizes, which threatened to close several mines, is a little better.

Stock at the mine is stated to be \$1.75 for screened and \$1.25 for straight. Other grades are: Lump, \$4.50; domestic lump, \$3.75; stone, \$3.75; nut, \$3.50. Retail prices are: \$9.50, \$9, \$8.50 and \$8 respectively.

Ohio Steam-Coal Market Slow

Large consumers of steam coals in the Columbus market are buying only for current needs and are showing little indication of increasing surplus stocks. The market, however, is absorbing all steam sizes although there is little special demand and prices continue low. The larger production of lump, rather than a reduction in demand, has forced lower prices for screenings. The railroads have eased up in buying because of the belief that there will be a satis-

factory agreement on the wage scale. Domestic trade is rather brisk. Users of these coals are buying in small lots, but retail dealers are generally busy. Pocahontas is showing considerable strength.

Production in the Ohio fields is better, with an output of about 30 per cent in the southern Ohio field. There have been several small strikes in the Hocking Valley district, resulting in a curtailed production.

Contracting for steam sizes is slow. Utilities are buying but not as heavily as earlier in the year, while several of the larger utilities in central Ohio are reported out of the market because of storage-pile fires.

The Cleveland market is sluggish with demand dull. Prices show no change from the previous week. Production in the eastern Ohio district for the week ended Feb. 9 was about 393,000 tons.

All attention at Cincinnati has been centered on the conference in Florida and buyers have been rather timid about placing orders. As a result of this condition there is some unsteadiness in the domestic market, both for smokeless and high-volatile. In the low-volatile market there has been less demand for "car numbers" from the West. On the other hand, the steady business in the Pocahontas and New River fields put the local sales agents in a position where they are selling now on a March delivery basis. Special coals are quoted as follows: Egg, \$3.25@3.50, and lump, \$3.75@4.

Pittsburgh coal operators are watching the Jacksonville conference carefully and the prediction in the trade is that if the present scale is continued the union coal mines, as a body, will have rather little business during the period, except as railroads may be unable to serve fully the non-union mines.

Altoona reports considerable correspondence and conferring on contracts, but not many being signed. A slight increase in production in central Pennsylvania was reported during the week ended Feb. 9, the loadings amounting to 16,597 cars as compared with 15,266 cars the previous week.

But little soft-coal buying is being done at Buffalo and there is little optimism.

New England Shows Slight Improvement

In New England there are few visible signs of improvement. There is scattering inquiry for small lots, but a close canvass of buyers in this territory discloses no prospect of comprehensive business for weeks to come. Several factors are offering No. 1 Navy standard grades from the Southern field at \$6.25@6.75 per gross ton on cars, but the larger consumers know that any quantity, however small, can be had at not over \$6. There is therefore little confidence in present quotations, and not even the possibility of labor troubles in April will induce more than hand-to-mouth purchases.

At Hampton Roads there is a steady increase in receipts from the mines, a condition that is reflected in an occasional price of less than \$4.75 per gross ton f.o.b. vessel. The agencies are combing over the market with great care in the effort to place spot coal, but aside from deliveries on contract there is little doing coastwise. Almost nothing is heard of contract engagements for the year beginning April 1, but doubtless many of the arrangements now in force will be renewed through the same channels from month to month, if not for the twelve-month period.

All-rail from central Pennsylvania the market is in the same quiet state that has obtained since last summer. Poca-

hontas and New River via Hampton Roads are still low enough in price at rehandling points here to exclude all-rail deliveries from the largest part of this territory. Medium grades in the Clearfield district can still be had at less than \$2 per net ton at the mines, and not even quality coals from Cambria County command more than \$2.75@2.90. Now and then there is an occasional call for screened coal to take the place of anthracite, the retail dealer being in position to offer high grade fuel at from \$3 to \$4 less than the present retail price of hard coal.

Inland Demand for Soft Coal Better

The topic of comment along the Atlantic seaboard is the Jacksonville conference. There has been no change in conditions. Buying at tidewater is slow, but demand from the inland is better. Some contracts have been reported as closed but a number of consumers are holding back awaiting developments. Increased inquiries have resulted in more orders and there has been some extra buying. Some of the railroads are considering new contracts to take the place of those that will expire soon. While the cotton and woolen textiles are quiet there is a better feeling in some of the other industries and the trade is encouraged to some extent. There has been no distinct line of improvement shown in the Baltimore market with the exception of more inquiries.

Anthracite Market Quiet

There is no real activity in the anthracite market. Domestic coals are plentiful and, contrary to past years, there has been no rush to replenish stocks. Mild weather conditions have not caused heavy consumption and producers of independent coals find it difficult in some instances to keep their product moving. The demand centers around stove coal, but there is a good demand for chestnut. Egg and pea are moving slowly and it is reported that some pea is being stored by the producers. The steam coals are easier but in good demand. Barley is the strongest of the three sizes and the better grades are being quoted at more than company circular. Some Welsh anthracite is being received at Baltimore, but the tonnage is not large.

Spot Furnace Coke Stiffens

Production of beehive coke during the week ended Feb. 9 was 287,000 net tons, as compared with 264,000 tons in the previous week and 359,000 tons during the corresponding week of last year. Spot furnace coke is stiffer in the Connellsville district and second-quarter contracting is reported easier. Recent buying of spot furnace coke cleaned up floating supplies very well and there were some prompt lots sold, which absorbed the extra production beyond regular contract requirements. As a result offerings in the spot market are very light. Heating coke has stiffened lately, some production being cut off on account of low prices.

Foreign Market
And Export News

Strike of Dock Workers Likely to Affect
British Mines; Output Increases

While not yet affected by the dock workers' strike, which became effective at noon Feb. 16, it is expected that unless work is resumed soon the South Wales coal mines will be compelled to suspend operations, due principally to the scarcity of props and other mine timber.

Congestion at the docks is reported as steadily growing and many vessels are reported waiting for cargoes. Rail service has been retarded, but this did not prevent the mines from producing 5,245,000 tons of coal during the week ended Feb. 2, according to a cable to *Coal Age*. This was 528,000 tons more than was produced during the previous week but a decrease of 603,000 tons when compared with the output of 5,848,000 tons during the week ended Jan. 19.

There is no indication at present of a resumption of the third working shift in the mines. There is a good foreign demand for coal and prices are stiffer. Best Admiralty grades are being quoted at 30s. 6d. @ 31s. 6d.; bunker smalls at 21s. @ 23s.; cargo smalls at 18s. @ 20s.; mixed bunker throughs at 23s. @ 28s., and coke for export at 47s. 6d. @ 57s. 6d.

The settlement of the recent railway dispute came too late to enable the Welsh market to show any material improvement. At that time about 70 per cent of the collieries were operating and others were already closing down. The railway companies, however, got into their stride quickly and other mines were saved from suspending operations. As a result the market is very uncertain but operators are asking slightly increased prices for forward business.

Similar conditions exist in the Newcastle market, though there is considerable pressure for prompt delivery. The output has been well maintained and not many pits have had to close down. Stocks accumulated during the

strike are now being cleared at firm prices.

Various public corporations on the Continent are placing contracts for quantities ranging up to 10,000 tons.

Export Permits to Insure French Coal
for Home Needs

Permits regulating the export of French coal have been re-established in order to save the largest portion for home consumption and to avoid the necessity for buying foreign fuel. These permits will be effective throughout the country and also will apply to foreign steamers entering French ports for replenishing their supply of fuel.

The prices of all kinds of coal were reduced 3 fr. effective Feb. 1, as a result of the request of the French authorities; this despite the higher cost of labor and raw materials of all kinds. To the railway strike in Great Britain occasioned considerable uneasiness in regard to prices and arrivals fell off to a marked degree for a while. Transportation difficulties are interfering with the arrival of Belgian coals, but in France both land and water traffic have greatly improved but are still below normal.

An improvement in the supply of metallurgical coke is reported but the receipts from Great Britain and Belgium are slightly smaller because of the railway and dock troubles. The French authorities have fixed a price of 143.5 fr. for German coke delivered at the frontier.

Hampton Roads Market Dull

Business at Hampton Roads was generally dull last week, with an occasional good order reported. Foreign movements were fairly brisk, but mostly on old contracts. Inquiries for

foreign business were not numerous.

Bunker trade held its own, with a substantial increase in general shipping. Coastwise business showed little increase, though movement was fairly active chiefly on old orders. The spot trade was generally fair.

Prices about held their own, although various price levels were being maintained by shippers who desired to get coal off of demurrage. The tone of the market was dull.

Traffic News

West Virginia Intervenes in Lake Rate Hearing

The State of West Virginia, through its Public Service Commission, has taken a hand in protecting coal cargo rates to the lakes by asking to be permitted to intervene in the petition of the Pittsburgh Coal Producers Association and the Pittsburgh Vein Operators Association against the Ashland Coal & Iron Ry. for a change in lake rates. The West Virginia Public Service Commission was represented at the hearings in Washington during the second week of February by B. S. Stathers, a member of the commission, and F. Livezy, general counsel for the commission.

In its petition filed with the Interstate Commerce Commission, the West Virginia Public Service Commission sets forth that "for many years the rates of rail carriers have had an established relationship as between the coal-mining districts of the State of West Virginia and other districts shipping lake cargo coal, including the districts represented by complainants, and petitioner believes complainants seek by this proceeding to change such relationship and to have established rates which will give complainants or the operators represented by complainants an advantage over operators in the State of West Virginia, in the sale of lake cargo coal, and thus prevent the operators of the State of West Virginia from competing in the sale and marketing of such coal."

N. & W. Buys 4,000 Coal Cars

Among the largest equipment orders since the beginning of the year was that of 4,000 seventy-ton hopper cars placed Feb. 13 by the Norfolk & Western R.R. While no statement was given as to the total amount involved, it was estimated that the order would equal about \$12,000,000. One-half of the order went to the Ralston Car Co. The Pressed Steel Car Company received an order for 1,000 cars, and the remaining 1,000 cars will be constructed by the Virginia Bridge & Iron Co.

Would Extend Coal Road In Pennsylvania

The Conemaugh & Black Lick Railroad Co. has applied to the Interstate Commerce Commission for authority to acquire and operate an existing line of railroad in Cambria County, Pennsylvania and to construct and operate a 16-mile extension of that line so as to form a direct connection between the main line of the Pennsylvania and the line of the Baltimore & Ohio at Johnstown. In addition to facilitating the handling and interchange of freight, it is stated that the extension will "open up new territory for manufacturing sites and for the mining of coal, fireclay and other minerals."

Asks Exemption from Rate Order

The Central Railroad of New Jersey has petitioned the Interstate Commerce Commission that it be exempted from the provisions of the so-called "New England rate" order, handed down in 1922 and upheld in a decision of the U. S. Supreme Court a year ago.

By the terms of the New England rate decision the terminal New England railroads were granted an increase in their proportionate share of through rates on shipments from other sections of the country, the cost of the extra apportionment being pro-rated among the carriers contributing to such freight movement. The plea of the Jersey Central is based on the contention that it is more properly a terminal railroad than a through freight line and that, moreover, its earnings are not on a level sufficiently high to enable it to bear its share of the burden.

Hearings on the petition are expected to be held within the next few weeks, and it is understood that other roads are considering taking action similar to that of the Jersey Central.

New Freight Record in 1923

A record amount of freight traffic was carried by the railroads of the country in 1923, according to complete reports filed with the Bureau of Railway Economics. Traffic handled during 1923 amounted to 457,589,846,000 net ton miles, which exceeded by 2.3 per cent the 1920 total, the previous high record. Compared with 1922, this was an increase of 21.7 per cent. For the month of December, however, there was a decrease of 7.9 per cent, in comparison with the same month in 1922. The average load per freight car in 1923 amounted to 27.9 tons, or one ton above the average for 1922, but a decrease of 1.4 tons compared with the record average established in 1920.

Revised Rates in Effect March 1

The Louisville & Nashville R.R. has notified the Alabama Public Service Commission that it will put into effect March 1 the revised interstate coal and coke rates prescribed in the commission's recent order.

Industrial Notes

The J. B. Engineering Sales Co., Connecticut sales representatives of the Conveyors Corporation of America, Chicago, have moved their office from Hartford to Chamber of Commerce Building, New Haven, Conn. This firm handles the sales of American steam-jet, ash conveyors and other power-plant and engineering specialties.

The St. Louis Steel Casting Co., will open a new foundry for the production of commercial steel castings March 15, at 100 Malt St., St. Louis, Mo. The officers of the new company are Joseph Teipel, president; W. F. Heinecke, vice-president; W. F. Exner, secretary, and F. G. Langbein, treasurer.

Obituary

Robert Fleming, president of the Fleming Coal Co. and of the Banner Coal Co., both located at Bannervane, Va., died of Bright's disease at Norton, Va., Feb. 12, at the age of 68. Born in Scotland he came to this country with his parents when 15 years old, the family settling in Pennsylvania. In his early youth he worked in the coal fields of Pennsylvania, later removing to Iowa, where he spent several years trying to develop a mine in the coal district of that state. In the early nineties he went to Norton, Va., and became a pioneer in the development of the Clinch Valley, opening the first coal mine in the valley, the Virginia Gas Coal Co., in Tazewell County.

S. M. Cawood, former sheriff of Harlan County, Kentucky, coal operator, and prominent business man, died suddenly on Jan. 31, at his winter home in Asheville, N. C., where he had gone for his health. A wife and five children survive. Death was due to a sudden attack of heart trouble.

Coming Meetings

Upper Potomac Coal Association. Annual meeting March 3, Cumberland, Md. Secretary, J. F. Palmer, Cumberland, Md.

Northwestern Pennsylvania Coal Operators' Association. Annual meeting March 4. Butler, Pa. Secretary, T. F. Diefenderfer, Butler, Pa.

Canadian Institute of Mining and Metallurgy. Annual meeting March 5-7, King Edward Hotel, Toronto, Ontario, Canada. Secretary, G. C. Mackenzie, Drummond Building, Montreal, Quebec, Canada.

New England Coal Dealers' Association. Annual meeting March 20-21, Boston, Mass. President, W. A. Clark, Boston, Mass.
